#### Abstract

Bilevel optimization has arisen as a powerful tool for many machine learning problems such as meta-learning, hyper-parameter optimization, reinforcement learning, etc. In this paper, we investigate the nonconvex-strongly-convex bilevel optimization problem, and propose two novel algorithms named deter BiO and stocBiO respectively for the deterministic and stochastic settings. At the core design of deterBiO is the construction of a low-cost and easy-to-implement hyper-gradient estimator via a simple back-propagation. In addition, stocBiO updates with the mini-batch data sampling rather than the existing single-sample schemes, where a sample-efficient Hessian inverse estimator is proposed. We provide the finite-time convergence guarantee for both algorithms, and show that they outperform the best known computational complexities orderwisely with respect to the condition number $\kappa$ and/or the target accuracy $\epsilon$. We further demonstrate the superior efficiency of the proposed algorithms by the experiments on meta-learning and hyper-parameter optimization.

## 1 Introduction

Bilevel optimization has received significant attention recently and become an influential framework in various machine learning applications including meta-learning (Franceschi et al., 2018; Bertinetto et al., 2018, Rajeswaran et al., 2019; Ji et al., 2020a), hyper-parameter optimization (Franceschi et al., 2018; Shaban et al., 2019, Feurer and Hutter, 2019), reinforcement learning (Konda and Tsitsiklis, 2000; Hong et al., 2020), and signal processing (Kunapuli et al. 2008, Flamary et al., 2014). A general bilevel optimization takes the following formulation.

$$
\begin{equation*}
\min _{x \in \mathbb{R}^{p}} \Phi(x):=f\left(x, y^{*}(x)\right) \quad \text { s.t. } \quad y^{*}(x)=\underset{y \in \mathbb{R}^{q}}{\arg \min } g(x, y), \tag{1}
\end{equation*}
$$

where the upper- and inner-level functions $f$ and $g$ are both jointly continuously differentiable. The goal of eq. (1) is to minimize the objective function $\Phi(x)$ w.r.t. $x$, where $y^{*}(x)$ is obtained by solving the lower-level minimization problem. In this paper, we focus on the setting where the lower-level function $g$ is strongly convex with respect to (w.r.t.) $y$, and the upper-level objective function $\Phi(x)$ is nonconvex w.r.t. $x$. Such types of geometrics commonly exist in many applications including meta-learning and hyper-parameter optimization,
where $g$ corresponds to an empirical loss with a strongly-convex regularizer and $x$ are parameters of neural networks.

A broad collection of algorithms have been proposed to solve such types of bilevel optimization problems, which inlcude constraint-based methods (Hansen et al., 1992, Shi et al. 2005, Moore, 2010), implicit gradient based methods (Pedregosa, 2016; Gould et al. 2016; Ghadimi and Wang, 2018), and dynamic system based methods (Maclaurin et al., 2015; Franceschi et al. 2017, 2018; Shaban et al., 2019). Most of these works have focused on the asymptotic convergence analysis except that Ghadimi and Wang (2018) provided the finite-time convergence analysis for their proposed bilevel approximation (BA) method. However, to estimate the hyper-gradient $\nabla \Phi(x)$, BA requires an exact computation of a Hessian inverse and high-order partial derivatives, which is often computationally expensive and and hard to implement in deep learning applications such as meta-learning.

- Thus, the first focus of this paper is to design a new bilevel optimization algorithm, which achieves better efficiency in practice, is easy to implement in deep learning, and more importantly, has the finite-time performance guarantee with order-level lower computational complexity.
The stochastic bilevel optimization often occurs in applications where fresh data need to be sampled as the algorithms run (e.g., reinforcement learning (Hong et al., 2020)) or the sample size of training data is large (e.g., hyper-parameter optimization (Franceschi et al., 2018), Stackelberg game (Roth et al., 2016)). Typically, the corresponding objective function is given by

$$
\begin{align*}
& \min _{x \in \mathbb{R}^{p}} \Phi(x)=f\left(x, y^{*}(x)\right):=\left\{\begin{array}{l}
\mathbb{E}_{\xi}\left[F\left(x, y^{*}(x) ; \xi\right)\right] \\
\frac{1}{n} \sum_{i=1}^{n} F\left(x, y^{*}(x) ; \xi_{i}\right)
\end{array}\right. \\
& \text { s.t. } \quad y^{*}(x)=\underset{y \in \mathbb{R}^{q}}{\arg \min } g(x, y):=\left\{\begin{array}{l}
\mathbb{E}_{\zeta}\left[G\left(x, y^{*}(x) ; \zeta\right)\right] \\
\frac{1}{m} \sum_{i=1}^{m} G\left(x, y^{*}(x) ; \zeta_{i}\right),
\end{array}\right. \tag{2}
\end{align*}
$$

where $f(x, y)$ and $g(x, y)$ take either the expectation form w.r.t. the random variables $\xi$ and $\zeta$ or the finite-sum form over given data $\mathcal{D}_{n, m}=\left\{\xi_{i}, \zeta_{j}, i=1, \ldots, n ; j=1, \ldots, m\right\}$ often with large sizes $n$ and $m$. During the optimization process, the algorithms sample data batch via the distributions of $\xi$ and $\zeta$ or from the set $\mathcal{D}_{n, m}$. For such a stochastic setting, Ghadimi and Wang (2018) proposed a bilevel stochastic approximation (BSA) method via single-sample gradient and Hessian estimates. Based on such a method, Hong et al. (2020) further proposed a two-timescale stochastic approximation (TTSA), and showed that TTSA achieves a better trade-off between the complexities of inner- and outer-loop optimization stages than BSA.

- The second focus of this paper is to design a more sample-efficient algorithm for bilevel stochastic optimization, which achieves an order-level lower computational complexity over BSA and TTSA.

### 1.1 Main Contributions

Our main contributions lie in proposing faster algorithms for the nonconvex-strongly-convex bilevel deterministic and stochastic optimization problems with provably order-level lower computational complexity. Our analysis involves several new developments, which can be of independent interest.

We first propose a deterministic bilevel optimizer (deterBiO) for solving the problem in eq. (1). Unlike the BA Ghadimi and Wang, 2018) method that requires an exact Hessian inverse computation, our method constructs a hyper-gradient estimator (which computes Hessian rather than Hessian inverse) via a simple back-propagation over the inner loop, and is easy to implement in deep learning applications. As shown in Table 1, the gradient complexities of our algorithm w.r.t. $f$ and $g$ to attain an $\epsilon$-accurate stationary point improve those of BA (Ghadimi and Wang, 2018) by an order of $\kappa$ and $\kappa \epsilon^{-1 / 4}$, respectively, where $\kappa$

Table 1: Comparison of bilevel deterministic optimization algorithms.

| Algorithm | $\operatorname{Gc}(f, \epsilon)$ | $\operatorname{Gc}(g, \epsilon)$ | $\operatorname{Hxy}(g, \epsilon)$ | $\operatorname{Hyy}(g, \epsilon) / \operatorname{Hyy}^{\text {inv }}(g, \epsilon)^{*}$ |

| stocBiO (ours) | $\mathcal{O}\left(\kappa^{5} \epsilon^{-2}\right)$ | $\mathcal{O}\left(\kappa^{9} \epsilon^{-2}\right)$ | $\mathcal{O}\left(\kappa^{5} \epsilon^{-2}\right)$ | $\widetilde{\mathcal{O}}\left(\kappa^{6} \epsilon^{-2}\right)$ |

* We use $\operatorname{poly}(\kappa)$ because Hong et al. (2020) do not provide the dependences on $\kappa$.
is the condition number. For the hyper-gradient estimation, our algorithm needs totally $\widetilde{\mathcal{O}}\left(\kappa^{4} \epsilon^{-1}\right)$ Hessian computations, whereas BA requires the same number of Hessian inverse computations (where each Hessian inverse is much more costly than each Hessian computationally). Technically, our analysis develops a novel characterization on the convergence rate of the back-propagation based hyper-gradient estimator.

We then propose a stochastic bilevel optimizer (stocBiO) to solve the problem eq. (2). Our algorithm features a mini-batch hyper-gradient estimation via implicit differentiation, where the core design involves a warm-start initialization for the inner loop and a sample-efficient mini-batch Hessian inverse estimator. As shown in Table 2, the gradient complexities of our proposed algorithm w.r.t. $F$ and $G$ improve upon those of BSA Ghadimi and Wang, 2018 by an order of $\kappa$ and $\epsilon^{-1}$, respectively. In addition, the second-order derivative complexity $\operatorname{Hxy}(G, \epsilon)$ of our algorithm improves that of BSA by an order of $\kappa$. In terms of the accuracy $\epsilon$, our gradient and second-order derivative complexities improve those of TTSA (Hong et al., 2020) by an order of $\epsilon^{-0.5}$ and $\epsilon^{-0.5}$, respectively.

We further provide the theoretical complexity guarantee of deterBiO and stocBiO in meta-learning and hyper-parameter optimization, and demonstrate their superior efficiency by experiments.

### 1.2 Related Work

Bilevel optimization approaches: Bilevel optimization was first introduced by Bracken and McGill (1973). Since then, quite a few bilevel optimization algorithms have been proposed, which include but not limited to constraint-based methods (Shi et al., 2005, Moore, 2010), gradient-based methods (Pedregosa, 2016, Gould et al., 2016, Maclaurin et al., 2015, Franceschi et al., 2018, Ghadimi and Wang, 2018, Shaban et al., 2019, Hong et al. 2020, Liu et al., 2020, Li et al., 2020), etc. Among them, Ghadimi and Wang (2018); Hong et al. (2020) provided the finite-time complexity analysis for their proposed methods for the nonconvex-strongly-convex bilevel optimization problem. For such a problem, this paper proposes two novel algorithms respectively for the deterministic and stochastic settings with order-level lower computational complexity than the existing results.

Some works have studied other types of loss geometries. For example, Liu et al. (2020); Li et al. (2020)
assumed that the lower- and upper-level functions $g(x, \cdot)$ and $f(x, \cdot)$ are convex and strongly-convex, and provided an asymptotic analysis for their methods. Ghadimi and Wang (2018); Hong et al. (2020) studied the setting where $\Phi(\cdot)$ is strongly-convex or convex, and $g(x, \cdot)$ is strongly-convex.
Bilevel optimization in meta learning: Bilevel optimization framework has been successfully employed in meta-learning recently (Snell et al., 2017, Franceschi et al., 2018; Rajeswaran et al., 2019, Zügner and Günnemann, 2019; Ji et al. 2020ab b). For example, Snell et al. (2017) proposed a bilevel optimization procedure for meta-learning to learn a common embedding model for all tasks. Rajeswaran et al. (2019) reformulated the model-agnostic meta-learning (MAML) (Finn et al., 2017) as a bilevel optimization problem, and proposed iMAML via implicit gradient. This paper demonstrates the better efficiency of deterBiO than the existing representative methods in meta-learning.
Bilevel optimization in hyper-parameter optimization: Hyper-parameter optimization has become increasingly important as a powerful tool in the automatic machine learning (autoML) (Okuno et al., 2018; Yu and Zhu, 2020). Recently, various bilevel optimization algorithms have been proposed in the context of hyper-parameter optimization, which include implicit differentiation based methods (Pedregosa, 2016), dynamical system based methods via reverse or forward gradient computation (Franceschi et al., 2017, 2018; Shaban et al. 2019), etc. This paper demonstrates the superior efficiency of the proposed stocBiO algorithm in hyper-parameter optimization.

## 2 Proposed Algorithms

In this section, we propose two algorithms respectively for the deterministic and stochastic bilevel optimization problems, and describe the key design components involved in these algorithms.

### 2.1 Algorithm for Deterministic Bilevel Optimization

In order to efficiently solve the deterministic bilevel objective problem eq. (1), we propose a deterministic bilevel optimizer (deterBiO) as given in Algorithm 1 .
deterBiO updates in a nested-loop manner. At the beginning of each outer loop, the inner loop runs $T$ steps of gradient decent (GD) to find an approximation point $y_{k}^{T}$ close to $y^{*}\left(x_{k}\right)$. At the outer loop, deterBiO computes the gradient $\frac{\partial f\left(x_{k}, y_{k}^{T}\left(x_{k}\right)\right)}{\partial x_{k}}$ as an approximation of the hyper-gradient $\nabla \Phi\left(x_{k}\right)=\frac{\partial f\left(x_{k}, y^{*}\left(x_{k}\right)\right)}{\partial x_{k}}$ via back-propagation, where we write $y_{k}^{T}\left(x_{k}\right)$ because the output $y_{k}^{T}$ of the inner loop has a dependence on $x_{k}$ through the inner-loop iterative GD updates, and $x_{k}$ and $y_{k}^{0}$ are treated to be mutually-independent during the differentiation process at the $k^{t h}$ outer loop. Our design is easy to implement in deep learning applications such as meta-learning via the automatic differentiation package. The explicit form of the estimate $\frac{\partial f\left(x_{k}, y_{k}^{T}\left(x_{k}\right)\right)}{\partial x_{k}}$ is given by the following proposition via the chain rule.

Proposition 1. The gradient $\frac{\partial f\left(x_{k}, y_{k}^{T}\left(x_{k}\right)\right)}{\partial x_{k}}$ takes the following analytical form:

$$
\frac{\partial f\left(x_{k}, y_{k}^{T}\right)}{\partial x_{k}}=\nabla_{x} f\left(x_{k}, y_{k}^{T}\right)-\alpha \sum_{t=0}^{T-1} \nabla_{x} \nabla_{y} g\left(x_{k}, y_{k}^{t}\right) \prod_{j=t+1}^{T-1}\left(I-\alpha \nabla_{y}^{2} g\left(x_{k}, y_{k}^{j}\right)\right) \nabla_{y} f\left(x_{k}, y_{k}^{T}\right)
$$

where we set $\prod_{j=T}^{T-1}(\cdot)=I$ to simplify the notation.
Proposition 1 shows that the differentiation involves computations of second-order derivatives such as Hessian $\nabla_{y}^{2} g(\cdot, \cdot)$. Since efficient Hessian-free methods, e.g., conjugate-gradient (CG), have been successfully deployed in the existing automatic differentiation tools, the computations of second-order derivatives are efficient and scalable to the problem dimension. As a comparison, Ghadimi and Wang (2018) constructs the

```
Algorithm 1 Deterministic bilevel optimizer (deterBiO)
    Input: lower- and upper-level stepsizes \(\alpha, \beta>0\), initializations \(x_{0}\) and \(\left\{y_{k}^{0}, k=0, \ldots, K\right\}\).
    for \(k=0,1,2, \ldots, K\) do
        for \(t=1, \ldots, T\) do
            Update \(y_{k}^{t}=y_{k}^{t-1}-\alpha \nabla_{y} g\left(x_{k}, y_{k}^{t-1}\right)\)
        end for
        Compute gradient \(\frac{\partial f\left(x_{k}, y_{k}^{T}\right)}{x_{k}}\) via back-propagation w.r.t. \(x_{k}\)
        Update \(x_{k+1}=x_{k}-\beta \frac{\partial f\left(x_{k}, y_{k}^{T}\right)}{\partial x_{k}}\)
    end for
```

outer gradient using the implicit differentiation formulation, and requires to compute Hessian inverse $\left(\nabla_{y}^{2} g\right)^{-1}$ exactly and explicitly, which is harder to implement and much more costly than Hessian computation in our algorithm in deep learning applications.

### 2.2 Algorithm for Stochastic Bilevel Optimization

We propose a stochastic bilevel optimizer (stocBiO) in Algorithm 2 to solve the problem eq. (2). It has a double-loop structure similar to deterBiO, but runs $T$ steps of stochastic gradient decent (SGD) at the inner loop to obtain an approximated solution $y_{k}^{T}$. Note that we choose the initialization $y_{k}^{0}$ of each inner loop as the output $y_{k-1}^{T}$ of the preceding inner loop rather than a random start. Such a warm start allows us to back-propagate the tracking error $\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|$ to previous loops, and results in an improved computational complexity. Based on the output $y_{k}^{T}$ of the inner loop, stocBiO then constructs an outer-loop gradient estimate

$$
\begin{equation*}
\widehat{\nabla} \Phi\left(x_{k}\right)=\nabla_{x} F\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{F}\right)-\nabla_{x} \nabla_{y} G\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{G}\right) H^{\mathrm{inv}}\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{H}\right) \nabla_{y} F\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{F}\right) \tag{3}
\end{equation*}
$$

as an estimate of $\nabla \Phi\left(x_{k}\right)$ whose explicit form is given by the following proposition.
Proposition 2. Recalling the definition $\Phi(x):=f\left(x, y^{*}(x)\right)$, it holds that

$$
\begin{equation*}
\nabla \Phi\left(x_{k}\right)=\nabla_{x} f\left(x_{k}, y^{*}\left(x_{k}\right)\right)-\nabla_{x} \nabla_{y} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)\left[\nabla_{y}^{2} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)\right]^{-1} \nabla_{y} f\left(x_{k}, y^{*}\left(x_{k}\right)\right) \tag{4}
\end{equation*}
$$

An important component of our algorithm is the Hessian inverse estimator $H^{\text {inv }}(\cdot)$ in eq. (3) . Compared to the deterministic case, designing a sample-efficient Hessian inverse estimator in the stochastic case is more challenging. Using the Taylor expansion, we construct a mini-batch Hessian inverse estimator in Algorithm 3 which takes the form of

$$
\begin{equation*}
\text { (Hessian inverse estimator): } \quad H^{\mathrm{inv}}\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{H}\right)=\eta \sum_{q=0}^{Q} \prod_{j=1}^{q}\left(I-\eta \nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{j}\right)\right) \tag{5}
\end{equation*}
$$

where $\left\{\mathcal{B}_{j}, j=1, \ldots, Q\right\}$ are mutually-independent sample sets, and $Q$ and $\eta$ are constants. Instead of choosing the same batch sizes for all $\mathcal{B}_{j}, j=1, \ldots, Q$ in eq. (5), our analysis captures the different impact of components $\nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{j}\right), j=1, \ldots, Q$ on the Hessian inverse estimation variance, and inspires an adaptive and more efficient choice by setting $\left|\mathcal{B}_{j}\right|$ to decay exponentially with $j$. By doing so, we achieve an improved gradient and Hessian complexity.

```
Algorithm 2 Stochastic bilevel optimizer (stocBiO)
    Input: Stepsizes \(\alpha, \beta>0\), initializations \(x_{0}\) and \(y_{0}\).
    for \(k=0,1,2, \ldots, K\) do
        Set \(y_{k}^{0}=y_{k-1}^{T}\) if \(k>0\) and \(y_{0}\) otherwise
        for \(t=1, \ldots, T\) do
            Draw a sample batch \(\mathcal{S}_{t-1}\)
            Update \(y_{k}^{t}=y_{k}^{t-1}-\alpha \nabla_{y} G\left(x_{k}, y_{k}^{t-1} ; \mathcal{S}_{t-1}\right)\)
        end for
        Draw sample batches \(\mathcal{D}_{H}, \mathcal{D}_{G}, \mathcal{D}_{F}\)
        Construct Hessian inverse estimator via Algorithm 3
        Compute gradient estimate \(\widehat{\nabla} \Phi\left(x_{k}\right)\) via eq. (3)
        Update \(x_{k+1}=x_{k}-\beta \widehat{\nabla} \Phi\left(x_{k}\right)\)
    end for
```

## 3 Definitions and Assumptions

Let $z=(x, y)$ denote all parameters. For simplicity, suppose sample sets $\mathcal{S}_{t}$ for all $t=0, \ldots, T-1, \mathcal{D}_{G}$ and $\mathcal{D}_{F}$ have the sizes of $S, D_{g}$ and $D_{f}$, respectively. In this paper, we focus on the following types of loss functions for both the deterministic and stochastic cases.

Assumption 1. The lower-level function $g(x, y)$ is $\mu$-strongly-convex w.r.t. y and the total objective function $\Phi(x)=f\left(x, y^{*}(x)\right)$ is nonconvex w.r.t. $x$. For the stochastic setting, the same assumptions hold for $G(x, y ; \zeta)$ and $\Phi(x)$, respectively.

Since the objective function $\Phi(x)$ is nonconvex, algorithms are expected to find an $\epsilon$-accurate stationary point defined as follows.

Definition 1. We say $\bar{x}$ is an $\epsilon$-accurate stationary point for the objective function $\Phi(x)$ in eq. (2) if $\mathbb{E}\|\nabla \Phi(\bar{x})\|^{2} \leq \epsilon$, where $\bar{x}$ is the output of an algorithm.

In order to compare the performance of different bilevel algorithms, we adopt the following metrics of computational complexity.

Definition 2. For a function $f(x, y)$, let $\operatorname{Gc}(f, \epsilon)$ be the number of the partial gradient $\nabla_{x} f$ or $\nabla_{y} f, \operatorname{Hyy}(f, \epsilon)$ and $\mathrm{Hyy}^{-1}(f, \epsilon)$ be the number of Hessian $\nabla_{x}^{2} f$ or $\nabla_{y}^{2} f$ and Hessian inverse $\left(\nabla_{x}^{2} f\right)^{-1}$ or $\left(\nabla_{y}^{2} f\right)^{-1}$, respectively, and $\operatorname{Hxy}(f, \epsilon)$ be the number of second-order derivative $\nabla_{x} \nabla_{y} f$. For the stochastic case, similar metrics are adopted but w.r.t. the stochastic function $F(x, y ; \xi)$.

We take the following standard assumptions on the loss functions in eq. (2), which have been widely adopted in bilevel optimization (Ghadimi and Wang, 2018; Ji et al., 2020a).

Assumption 2. The loss function $f(z)$ and $g(z)$ satisfy

- $f(z)$ is $M$-Lipschitz, i.e., for any $z, z^{\prime},\left|f(z)-f\left(z^{\prime}\right)\right| \leq M\left\|z-z^{\prime}\right\|$.
- Gradients $\nabla f(z)$ and $\nabla f(z)$ are L-Lipschitz, i.e., for any $z, z^{\prime}$,

$$
\left\|\nabla f(z)-\nabla f\left(z^{\prime}\right)\right\| \leq L\left\|z-z^{\prime}\right\|,\left\|\nabla g(z)-\nabla g\left(z^{\prime}\right)\right\| \leq L\left\|z-z^{\prime}\right\|
$$

For the stochastic case, the same assumptions hold for $F(z ; \xi)$ and $G(z ; \zeta)$ for any given $\xi$ and $\zeta$.

As shown in Proposition 2, the gradient of the objective function $\Phi(x)$ involves the second-order derivatives $\nabla_{x} \nabla_{y} g(z)$ and $\nabla_{y}^{2} g(z)$. The following assumption imposes the Lipschitz conditions on such high-order derivatives, as also made in Ghadimi and Wang (2018).
Assumption 3. Suppose the derivatives $\nabla_{x} \nabla_{y} g(z)$ and $\nabla_{y}^{2} g(z)$ are $\tau$ - and $\rho$-Lipschitz, i.e.,

- For any $z, z^{\prime},\left\|\nabla_{x} \nabla_{y} g(z)-\nabla_{x} \nabla_{y} g\left(z^{\prime}\right)\right\| \leq \tau\left\|z-z^{\prime}\right\|$.
- For any $z, z^{\prime},\left\|\nabla_{y}^{2} g(z)-\nabla_{y}^{2} g\left(z^{\prime}\right)\right\| \leq \rho\left\|z-z^{\prime}\right\|$.

For the stochastic case, the same assumptions hold for $\nabla_{x} \nabla_{y} G(z ; \zeta)$ and $\nabla_{y}^{2} G(z ; \zeta)$ for any $\zeta$.
As typically adopted in the analysis for stochastic optimization (Wang et al. 2018; Ji et al., 2019), we make the following bounded-variance assumption for the lower-level stochastic function $G(z ; \zeta)$.

Assumption 4. $\nabla G(z ; \zeta)$ has a bounded variance, i.e., $\mathbb{E}_{\xi}\|\nabla G(z ; \zeta)-\nabla g(z)\|^{2} \leq \sigma^{2}$ for some $\sigma$.

## 4 Main Results for Bilevel Optimization

### 4.1 Deterministic Bilevel Optimization

We first characterize an important estimation property of the outer-loop gradient estimator $\frac{\partial f\left(x_{k}, y_{k}^{T}\right)}{\partial x_{k}}$ in Algorithm 1 for approximating the true gradient $\nabla \Phi\left(x_{k}\right)$ based on Proposition 1
Proposition 3. Suppose Assumptions 1, 2and 3 hold. Choose $\alpha \leq \frac{1}{L}$. Then, we have

$$
\begin{aligned}
\left\|\frac{\partial f\left(x_{k}, y_{k}^{T}\right)}{\partial x_{k}}-\nabla \Phi\left(x_{k}\right)\right\| \leq & \left(\frac{L(L+\mu)(1-\alpha \mu)^{\frac{T}{2}}}{\mu}+\frac{2 M(\tau \mu+L \rho)}{\mu^{2}}(1-\alpha \mu)^{\frac{T-1}{2}}\right)\left\|y_{k}^{0}-y^{*}\left(x_{k}\right)\right\| \\
& +\frac{L M(1-\alpha \mu)^{T}}{\mu}
\end{aligned}
$$

Proposition 3 shows that the gradient estimation error $\left\|\frac{\partial f\left(x_{k}, y_{k}^{T}\right)}{\partial x_{k}}-\nabla \Phi\left(x_{k}\right)\right\|$ decays exponentially w.r.t. the number $T$ of the inner-loop steps. The proof of Proposition 3 needs to characterize the rate of the sequence $\left(\frac{\partial y_{k}^{t}}{\partial x_{k}}, t=0, \ldots, T\right)$ converging to $\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}$ via the differentiation over all corresponding points along the inner-loop GD path as well as the optimality of the point $y^{*}\left(x_{k}\right)$.

Based on Proposition 3, we next characterize the convergence and complexity performance of the proposed deterBiO algorithm. Let $\kappa=\frac{L}{\mu}$ denote the condition number.
Theorem 1. Suppose Assumptions 1, 2] and 3 hold. Define a smoothness parameter $L_{\Phi}=L+\frac{2 L^{2}+\tau M^{2}}{\mu}+$ $\frac{\rho L M+L^{3}+\tau M L}{\mu^{2}}+\frac{\rho L^{2} M}{\mu^{3}}=\Theta\left(\kappa^{3}\right)$ and choose the outer stepsize $\beta=\frac{1}{4 L_{\Phi}}$ and $T=\log \left(\max \left\{\frac{3 L M}{\mu}, 9 \Delta L^{2}(1+\right.\right.$ $\left.\left.\left.\frac{L}{\mu}\right)^{2}, \frac{36 \Delta M^{2}(\tau \mu+L \rho)^{2}}{(1-\alpha \mu) \mu^{4}}\right\} \frac{9}{2 \epsilon}\right) / \log \frac{1}{1-\alpha \mu}=\Theta\left(\kappa \log \frac{1}{\epsilon}\right)$. Then, we have

$$
\frac{1}{K} \sum_{k=0}^{K-1}\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2} \leq \frac{16 L_{\Phi}\left(\Phi\left(x_{0}\right)-\inf _{x} \Phi(x)\right)}{K}+\frac{2 \epsilon}{3}
$$

In order to achieve an $\epsilon$-accurate stationary point, we have

- Gradient complexity: $\operatorname{Gc}(f, \epsilon)=\mathcal{O}\left(\kappa^{3} \epsilon^{-1}\right), \operatorname{Gc}(g, \epsilon)=\mathcal{O}\left(\kappa^{4} \epsilon^{-1} \log \left(\frac{1}{\epsilon}\right)\right)$.
- High-order complexity: $\operatorname{Hxy}(g, \epsilon)=\mathcal{O}\left(\kappa^{4} \epsilon^{-1} \log \frac{1}{\epsilon}\right), \operatorname{Hyy}(g, \epsilon)=\mathcal{O}\left(\kappa^{4} \epsilon^{-1} \log \frac{1}{\epsilon}\right)$.

It can be seen from Table 1 that the gradient complexity w.r.t. $f$ and $g$ of our algorithm improves that of BA Ghadimi and Wang 2018) (eq. (2.30) therein) by an order of $\kappa$ and $\kappa \epsilon^{-1 / 4}$. In contrast to BA Ghadimi and Wang, 2018) that requires computations of Hessian inverse, our algorithm requires only the computations of Hessian (at the same number), which are much more efficient.

### 4.2 Stochastic Bilevel Optimization

We first characterize the bias and variance of the Hessian inverse estimator $H^{\mathrm{inv}}\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{H}\right)$ in the following proposition.

Proposition 4. Suppose Assumptions 1, 2and 3 hold. Let the constant $\eta \leq \frac{1}{L}$ and choose the batch sizes $\left|\mathcal{B}_{j}\right|=B Q(1-\eta \mu)^{j-1}$ for $j=1, \ldots, Q$, where $B \geq \frac{1}{Q(1-\eta \mu)^{Q-1}}$. Then, the bias satisfies

$$
\begin{equation*}
\left\|\mathbb{E}_{\mathcal{D}_{H}} H^{\mathrm{inv}}\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{H}\right)-\left[\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right]^{-1}\right\| \leq \mu^{-1}(1-\eta \mu)^{Q} \tag{6}
\end{equation*}
$$

Furthermore, the estimation variance is given by

$$
\begin{equation*}
\mathbb{E}_{\mathcal{D}_{H}}\left\|H^{\mathrm{inv}}\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{H}\right)-\left[\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right]^{-1}\right\|^{2} \leq \frac{2 \eta^{2} L^{2}}{\mu^{2}} \frac{1}{B}+\frac{2(1-\eta \mu)^{2 Q+2}}{\mu^{2}} \tag{7}
\end{equation*}
$$

Proposition 4 shows that if we choose $Q$ and $B$ at an order level of $\mathcal{O}\left(\log \frac{1}{\epsilon}\right)$ and $\mathcal{O}(1 / \epsilon)$, the bias and variance are smaller than $\mathcal{O}(\epsilon)$, and the required number of samples is $\sum_{j=1}^{Q} B Q(1-\eta \mu)^{j-1}=\mathcal{O}\left(\epsilon^{-1} \log \frac{1}{\epsilon}\right)$. Note that the chosen batch size $\left|\mathcal{B}_{j}\right|$ exponentially decays w.r.t. $j$. As a comparison, the uniform choice of all $\left|\mathcal{B}_{j}\right|$ would yield a worse complexity of $\mathcal{O}\left(\epsilon^{-1}\left(\log \frac{1}{\epsilon}\right)^{2}\right)$.

We next provide the convergence and complexity analysis for the proposed stocBiO algorithm for the case where the objective function $\Phi(x):=f\left(x, y^{*}(x)\right)$ is nonconvex.

Theorem 2. Suppose Assumptions 1, 2, 3 and 4 hold. Define $L_{\Phi}=L+\frac{2 L^{2}+\tau M^{2}}{\mu}+\frac{\rho L M+L^{3}+\tau M L}{\mu^{2}}+\frac{\rho L^{2} M}{\mu^{3}}$, and choose $\beta=\frac{1}{4 L_{\Phi}}$ and $\eta<\frac{1}{L}$. Set $T \geq \max \left\{\frac{\log \left(12+\frac{48 \beta^{2} L^{2}}{\mu^{2}}\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2}\right)}{2 \log \left(\frac{L+\mu}{L-\mu}\right)}, \frac{\log \left(\sqrt{\beta}\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)\right)}{\log \left(\frac{L+\mu}{L-\mu}\right)}\right\}$. Then, we have

$$
\begin{gather*}
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E}\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2} \leq \frac{32 L_{\Phi}\left(\Phi\left(x_{0}\right)-\inf _{x} \Phi(x)+\frac{5}{2}\left\|y_{0}-y^{*}\left(x_{0}\right)\right\|^{2}\right)}{K}+\frac{52 L^{2} M^{2}}{\mu^{2}}(1-\eta \mu)^{2 Q} \\
+\frac{40\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2}}{L \mu} \frac{\sigma^{2}}{S}+\frac{22 L^{2} M^{2}}{\mu^{2} D_{g}}+\frac{\left(8 \mu^{2}+22 L^{2}\right) M^{2}}{\mu^{2} D_{f}}+\frac{44 L^{2} M^{2}}{\mu^{2} B} . \tag{8}
\end{gather*}
$$

In order to achieve an $\epsilon$-accurate stationary point, we have

- Gradient complexity: $\operatorname{Gc}(F, \epsilon)=\mathcal{O}\left(\kappa^{5} \epsilon^{-2}\right), \operatorname{Gc}(G, \epsilon)=\mathcal{O}\left(\kappa^{9} \epsilon^{-2}\right)$.
- High-order complexity: $\operatorname{Hxy}(G, \epsilon)=\mathcal{O}\left(\kappa^{5} \epsilon^{-2}\right), \operatorname{Hyy}(G, \epsilon)=\mathcal{O}\left(\kappa^{6} \epsilon^{-2} \log \frac{\kappa^{2}}{\epsilon}\right)$.

Theorem 2 shows that stocBiO converges sublinearly with the convergence error decaying exponentially w.r.t. $Q$ and sublinearly w.r.t. the batch sizes $S, D_{g}, D_{f}$ for gradient estimation and $B$ for Hessian inverse estimation. In addition, it can be seen that the total number $T$ of the inner-loop steps is chosen at nearly a constant level, rather than a typical choice of $\Theta\left(\log \left(\frac{1}{\epsilon}\right)\right)$.

As shown in Table 2, the gradient complexities of our proposed algorithm in terms of $F$ and $G$ improve those of BSA in Ghadimi and Wang (2018) by an order of $\kappa$ and $\epsilon^{-1}$, respectively. In addition, the second-order derivative complexity $\operatorname{Hxy}(G, \epsilon)$ of our algorithm improves that of BSA by an order of $\kappa$. In terms of the accuracy $\epsilon$, our gradient and second-order derivative complexities improve those of TTSA in Hong et al. (2020) by an order of $\epsilon^{-0.5}$ and $\epsilon^{-0.5}$, respectively.

## 5 Applications to Meta-Learning

### 5.1 Meta-Learning with Common Embedding Model

Consider the few-shot meta-learning problem with $m$ tasks $\left\{\mathcal{T}_{i}, i=1, \ldots, m\right\}$ sampled from distribution $P_{\mathcal{T}}$. Each task $\mathcal{T}_{i}$ has a loss function $\mathcal{L}\left(\phi, w_{i} ; \xi\right)$ over each data sample $\xi$, where $\phi$ are the parameters of an embedding model shared by all tasks, and $w_{i}$ are the task-specific parameters. The goal of this framework is to find good parameters $\phi$ for all tasks, and building on the embedded features, each task then adapts its own parameters $w_{i}$ by minimizing its loss.

The model training takes a bilevel procedure. In the lower-level stage, building on the embedded features, the base learner of task $\mathcal{T}_{i}$ searches $w_{i}^{*}$ as the minimizer of its loss function over a training set $\mathcal{S}_{i}$. In the upper-level stage, the meta-learner evaluates the minimizers $w_{i}^{*}, i=1, \ldots, m$ on held-out test sets, and optimizes $\phi$ of the embedding model over all tasks. Specifically, let $\widetilde{w}=\left(w_{1}, \ldots, w_{m}\right)$ denote all task-specific parameters. Then, the objective function is given by

$$
\begin{align*}
& \min _{\phi} \mathcal{L}_{\mathcal{D}}\left(\phi, \widetilde{w}^{*}\right):=\frac{1}{m} \sum_{i=1}^{m} \underbrace{\frac{1}{\left|\mathcal{D}_{i}\right|} \sum_{\xi \in \mathcal{D}_{i}} \mathcal{L}\left(\phi, w_{i}^{*} ; \xi\right)}_{\mathcal{L}_{\mathcal{D}_{i}}\left(\phi, w_{i}^{*}\right): \text { task-specific upper-level loss }} \\
& \text { s.t. } \widetilde{w}^{*}=\underset{\widetilde{w}}{\arg \min } \mathcal{L}_{\mathcal{S}}(\phi, \widetilde{w})=\underset{\left(w_{1}, \ldots, w_{m}\right)}{\arg \min } \frac{1}{m} \sum_{i=1}^{m}(\underbrace{\frac{1}{\mathcal{S}_{i} \mid} \sum_{\xi \in \mathcal{S}_{i}} \mathcal{L}\left(\phi, w_{i} ; \xi\right)+\mathcal{R}\left(w_{i}\right)}_{\mathcal{L}_{\mathcal{S}_{i}}\left(\phi, w_{i}\right): \text { task-specific lower-level loss }}) \tag{9}
\end{align*}
$$

where $\mathcal{S}_{i}$ and $\mathcal{D}_{i}$ are the training and test datasets of task $\mathcal{T}_{i}$, and $\mathcal{R}\left(w_{i}\right)$ is a strongly-convex regularizer, e.g., $L^{2}$ regularization. Note that the lower-level problem is equivalent to solving each $w_{i}^{*}$ as a minimizer of the task-specific loss $\mathcal{L}_{\mathcal{S}_{i}}\left(\phi, w_{i}\right)$ for $i=1, \ldots, m$.

In practice, $w_{i}$ often corresponds to the parameters of the last linear layer of a neural network and $\phi$ are the parameters of the remaining layers (e.g., 4 convolutional layers in Bertinetto et al. (2018); Ji et al. (2020a)), and hence the lower-level function is strongly-convex w.r.t. $\widetilde{w}$ and the upper-level function $\mathcal{L}_{\mathcal{D}}\left(\phi, \widetilde{w}^{*}(\phi)\right)$ is generally nonconvex w.r.t. $\phi$. In addition, due to the small sizes of datasets $\mathcal{D}_{i}$ and $\mathcal{S}_{i}$ in few-shot learning, all updates for each task $\mathcal{T}_{i}$ use full gradient descent without data resampling. As a result, our proposed deterBiO in Algorithm 1 can be applied here.

In some applications where the number $m$ of tasks is large, it is more efficient to sample a batch $\mathcal{B}$ of i.i.d. tasks from $\left\{\mathcal{T}_{i}, i=1, \ldots, m\right\}$ at each meta (outer) iteration, and optimizes the mini-batch versions $\mathcal{L}_{\mathcal{D}}(\phi, \widetilde{w} ; \mathcal{B})=\frac{1}{|\mathcal{B}|} \sum_{i \in \mathcal{B}} \mathcal{L}_{\mathcal{D}_{i}}\left(\phi, w_{i}\right)$ and $\mathcal{L}_{\mathcal{S}}(\phi, \widetilde{w} ; \mathcal{B})=\frac{1}{|\mathcal{B}|} \sum_{i \in \mathcal{B}} \mathcal{L}_{\mathcal{S}_{i}}\left(\phi, w_{i}\right)$ instead. The following theorem provides the convergence analysis of deter BiO for this case.

Theorem 3. Suppose Assumptions 1, 2 and 3 hold and suppose each task loss $\mathcal{L}_{\mathcal{S}_{i}}\left(\phi, w_{i}\right)$ is $\mu$-strongly-convex w.r.t. $w_{i}$. Choose the same parameters $\beta, T$ as in Theorem 1. Then, we have

$$
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E}\left\|\nabla \Phi\left(\phi_{k}\right)\right\|^{2} \leq \frac{16 L_{\Phi}\left(\Phi\left(\phi_{0}\right)-\inf _{\phi} \Phi(\phi)\right)}{K}+\frac{2 \epsilon}{3}+\left(1+\frac{L}{\mu}\right)^{2} \frac{M^{2}}{8|\mathcal{B}|}
$$

where $\Phi(\phi):=\mathcal{L}_{\mathcal{D}}\left(\phi, \widetilde{w}^{*}(\phi)\right)$ and the constant $L_{\Phi}$ is given in Theorem 1.
Theorem 3 shows that compared to the full batch (i.e., without task sampling) case in eq. (9), the task sampling introduces a variance term $\mathcal{O}\left(\frac{1}{|\mathcal{B}|}\right)$ due to the stochastic nature of the algorithm.

### 5.2 Experiments

We compare the performance among the following four algorithms: deterBiO proposed in this paper, bilevel optimizer $\left.\mathrm{BA}\right|^{1}$ (Ghadimi and Wang, 2018), and two popular meta-learning algorithms MAML (Finn et al., 2017) and ANIL ${ }^{2}$ (Raghu et al. 2019). We conduct experiments over a 5 -way 5 -shot task on two benchmark datasets: FC100 and miniImageNet, and the results are averaged over 10 trails with different random seeds. Due to the space limitations, we provide the dataset description, model architectures, hyper-parameter settings and additional experiments in Appendix A.

Figure 1: Convergence rate of various algorithms on meta-learning. For each dataset, left plot: training accuracy v.s. running time; right plot: test accuracy v.s. running time.

It can be seen from Figure 1 that for both the miniImageNet and FC100 datasets, the proposed deterBiO algorithm converges much faster (nearly 2 times faster in Figure 1(a) than other competing algorithms in terms of both the training accuracy and test accuracy, and further achieves a better final test accuracy than ANIL and MAML. In addition, our experiments in Appendix A.3 show that deterBiO converges more stably than ANIL when the number of inner-loop steps increases.

## 6 Application to Hyper-parameter Optimization

### 6.1 Hyper-parameter Optimization

The goal of hyper-parameter optimization (Franceschi et al. 2018; Feurer and Hutter, 2019) is to search for representation or regularization parameters $\lambda$ to minimize the validation error evaluated over the learner's parameters $w^{*}$, where $w^{*}$ is the minimizer of the inner-loop regularized training error. Mathematically, the objective function is given by

$$
\begin{array}{ll}
\min _{\lambda} & \mathcal{L}_{\mathcal{D}_{\text {val }}}(\lambda)=\frac{1}{\left|\mathcal{D}_{\mathrm{val}}\right|} \sum_{\xi \in \mathcal{D}_{\mathrm{val}}} \mathcal{L}\left(w^{*}(\lambda) ; \xi\right) \\
\text { s.t. } & w^{*}(\lambda)=\underset{w}{\arg \min } \mathcal{L}_{\mathcal{D}_{\mathrm{tr}}}(w, \lambda):=\frac{1}{\left|\mathcal{D}_{\mathrm{tr}}\right|} \sum_{\xi \in \mathcal{D}_{\mathrm{tr}}}(\mathcal{L}(w ; \xi)+\mathcal{R}(w, \lambda)), \tag{10}
\end{array}
$$

where $\mathcal{D}_{\text {val }}$ and $\mathcal{D}_{\text {tr }}$ are validation and training data, respectively, $\mathcal{L}$ is the loss function, e.g., cross-entropy loss, and $\mathcal{R}(w, \lambda)$ is a regularizer parameterized by $\lambda$.

In practice, the lower-level function $\mathcal{L}_{\mathcal{D}_{\text {tr }}}(w, \lambda)$ is often strongly-convex w.r.t. $w$. For example, for the data hyper-cleaning application proposed by Franceschi et al. (2018); Shaban et al. (2019), the predictor is

[^0]modeled by a linear classifier, and the loss function $\mathcal{L}(w ; \xi)$ is convex w.r.t. $w$ and $\mathcal{R}(w, \lambda)$ is a strongly-convex regularizer, e.g., $L^{2}$ regularization. In addition, the sample sizes of $\mathcal{D}_{\text {val }}$ and $\mathcal{D}_{\mathrm{tr}}$ are often large, and stochastic algorithms are preferred for achieving better efficiency. As a result, the above hyper-parameter optimization falls into the stochastic bilevel optimization we study in eq. (2), and we can apply the proposed stocBiO algorithm here and Theorem 2 establishes its finite-time performance guarantee.

### 6.2 Experiments

We compare the performance among the proposed stocBiO method, BSA (Ghadimi and Wang, 2018), TTSA (Hong et al. 2020), BA (full batch) (Ghadimi and Wang, 2018) on a hyper-parameter optimization problem: data hyper-cleaning (Shaban et al. 2019) on MNIST (LeCun et al., 1998). The goal of data hyper-cleaning is to train a classier given that a portion of training labels have been corrupted. Specifically, with a probability $p$ (i.e., the corruption rate), each label of training data is replaced by a random class number. All results are averaged over 10 trails with different random seeds, and the best hyper-parameters are chosen for all comparison algorithms. The details of the objective function, the dataset description, and the bilevel optimization procedure can be found in Appendix B

Figure 2: Convergence rate of various algorithms on hyper-parameter optimization at different corruption rates. For each $p$, left plot: training loss v.s. running time; right plot: test loss v.s. running time.

Figure 3: Convergence rate of various algorithms on hyper-parameter optimization at the corruption rate $p=0.1$. Left plot: training loss v.s. running time; right plot: test loss v.s. running time.

It can be seen from Figure 2 and Figure 3 that our proposed stocBiO algorithm achieves the fastest convergence rate among all competing algorithms in terms of both the training loss and the test loss. In addition, it is observed that such an improvement is more significant when the corruption rate $p$ is smaller.

## 7 Conclusion

In this paper, we propose two novel algorithms for the nonconvex-strongly-convex bilevel optimization, and show that their computational complexities outperform the best known results order-wisely. We also provide the theoretical guarantee of the proposed algorithms in meta-learning and hyper-parameter optimization, and demonstrate their effectiveness via experiments. We anticipate that the finite-time analysis that we develop will be useful for analyzing other bilevel optimization problems with different loss geometries, and the proposed algorithms will be useful for other applications such as reinforcement learning and Stackelberg game.

## Supplementary Materials

## A Further Specifications on Meta-Learning Experiments

## A. 1 Datasets and Model Architectures

FC100 (Oreshkin et al., 2018) is a dataset derived from CIFAR-100 (Krizhevsky and Hinton, 2009), and contains 100 classes with each class consisting of 600 images of size 32. Following Oreshkin et al. (2018), these 100 classes are split into 60 classes for meta-training, 20 classes for meta-validation, and 20 classes for meta-testing. For all comparison algorithms, we use a 4 -layer convolutional neural networks (CNN) with four convolutional blocks, in which each convolutional block contains a $3 \times 3$ convolution ( padding $=1$, stride $=2$ ), batch normalization, ReLU activation, and $2 \times 2$ max pooling. Each convolutional layer has 64 filters.

The miniImageNet dataset (Vinyals et al. 2016) is generated from ImageNet (Russakovsky et al. 2015), and consists of 100 classes with each class containing 600 images of size $84 \times 84$. Following the repository (Arnold et al. 2019), we partition these classes into 64 classes for meta-training, 16 classes for meta-validation, and 20 classes for meta-testing. Following the repository (Arnold et al. 2019), we use a four-layer CNN with four convolutional blocks, where each block sequentially consists of a $3 \times 3$ convolution, batch normalization, ReLU activation, and $2 \times 2$ max pooling. Each convolutional layer has 32 filters.

## A. 2 Implementations and Hyper-parameter Settings

We adopt the existing implementations in the repository (Arnold et al., 2019) for ANIL and MAML. The Hessian inverse computation in the original BA is very costly, and hence we adopt a CG based inversion, e.g., eq. (7) in Rajeswaran et al. (2019). For all algorithms, we adopt Adam (Kingma and Ba, 2014) as the optimizer for the meta outer-loop update.

For the experiments in Figure 1(a), we choose the best parameters for all algorithms. Specifically, we choose the inner-loop stepsize as 0.1 , the outer-loop (meta) stepsize as 0.002 , the mini-batch size $|\mathcal{B}|$ for task sampling as 32 , and the number of inner-loop steps as 5 for both ANIL and deterBiO. For MAML, we choose the inner-loop stepsize as 0.5 , the outer-loop stepsize as 0.003 , the mini-batch size as 32 , and the number of inner-loop steps as 3 . For BA, we choose the inner-loop stepsize as 0.1 , the outer-loop (meta) stepsize as 0.002 , the mini-batch size $|\mathcal{B}|$ as 32 , and the number of CG steps as 5 .

For the experiments in Figure 1(b) we choose the inner-loop stepsize as 0.1, the outer-loop (meta) stepsize as 0.001 , the mini-batch size as 32 for all ANIL, deterBiO and BA. For MAML, we choose the inner-loop stepsize as 0.5 , the outer-loop stepsize as 0.001 , and the mini-batch size as 32 . We choose the number of inner-loop steps as 10 for both ANIL and deterBiO and 3 for MAML, and choose the number of CG steps as 5 for BA.

## A. 3 Additional Results for Meta Learning

In this subsection, we compare the robustness between deterBiO and ANIL (ANIL outperforms MAML in general) to the number of inner-loop steps. For the experiments in Figure 4 , we choose the inner-loop stepsize as 0.05 , the outer-loop (meta) stepsize as 0.002 , the mini-batch size as 32 , and the number $T$ of inner-loop steps as 10 for both ANIL and deterBiO. For the experiments in Figure 5 we choose the inner-loop stepsize as 0.1 , the outer-loop (meta) stepsize as 0.001 , the mini-batch size as 32 , and the number $T$ of inner-loop steps as 20 for both ANIL and deterBiO.

It can be seen from Figure 4 and Figure 5 that when the number of inner-loop steps become larger, i.e., $T=10$ for miniImageNet and $T=20$ for FC100, our proposed deterBiO converges stably with a small

Figure 4: Comparison of deterBiO and ANIL on miniImageNet dataset with $T=10$.

Figure 5: Comparison of deterBiO and ANIL on FC100 dataset with $T=20$.
variance, whereas ANIL suffers from a sudden descent at 1500s on miniImageNet and even diverges after 2000s on FC100.

## B Experiment Specifications on Hyper-Parameter Optimization

To handle the label corruption, the optimizer associates each training data sample $\left(x_{i}, y_{i}\right) \in \mathcal{D}_{t r}$ with a weight $\lambda_{i}$, and the training process aims to learn small weights on the corrupted data samples. Then, the bilevel optimization procedure is to first minimize the lower-level loss on corrupted train data w.r.t. all weights $\lambda=\left(\lambda_{i}, i \in \mathcal{D}_{\text {tr }}\right)$, and then minimize the upper-level loss on clean validation data $\mathcal{D}_{\text {val }}$ w.r.t. the classifier parameters $w$. Mathematically, the objective function is given by

$$
\begin{aligned}
& \min _{\lambda} E\left(\lambda, w^{*}\right)=\frac{1}{\left|\mathcal{D}_{\mathrm{val}}\right|} \sum_{\left(x_{i}, y_{i}\right) \in \mathcal{D}_{\mathrm{val}}} L\left(w^{*} x_{i}, y_{i}\right) \\
& \text { s.t. } \quad w^{*}=\underset{w}{\arg \min } \mathcal{L}(w, \lambda):=\frac{1}{\left|\mathcal{D}_{\mathrm{tr}}\right|} \sum_{\left(x_{i}, y_{i}\right) \in \mathcal{D}_{\mathrm{tr}}} \sigma\left(\lambda_{i}\right) L\left(w x_{i}, y_{i}\right)+c\|w\|^{2},
\end{aligned}
$$

where $L$ is the cross-entropy loss, $\sigma(\cdot)$ is the sigmoid fucntion, $c$ is the regularization parameter for the lower-level loss function. In the experiments, we choose $c=0.001$.

The experiments are conducted over MNIST (LeCun et al., 1998). The training, validation and test datasets respectively contain 20000,5000 and 10000 images sampled from MNIST. For the training dataset, we further replace each label by a random class number with a probability of $p$ such that partial training samples are corrupted.

We adopt Adam (Kingma and Ba, 2014) as the optimizer for the outer-loop update. For the proposed stocBiO, we choose the batch sizes $S, D_{g}, D_{f}$ to be 50 , and choose the batch size $\left|\mathcal{B}_{j}\right|=50 \times 0.9^{j}$ for $j=1, \ldots, Q$ in the hessian inverse estimation. Both BSA and TTSA take the single-sample sampling for both gradient, second-order derivative and Hessian inverse estimations. BA is a deterministic bilevel optimization algorithm and hence updates with exact (i.e., full-batch) gradient and Hessian computations. Other hyper-parameters of all comparison algorithms are listed in Table 3

Table 3: Parameters of all comparison algorithms

| Task | stocBiO | BA | BSA | TTSA |
| :--- | :--- | :--- | :--- | :--- |
| number of inner steps $T$ | 50 | 200 | 1000 | 1 |
| Outer stepsize $\beta$ | 1 | 1 | 1 | 1 |
| Inner stepsize $\alpha$ | 0.1 | 0.1 | 0.003 | 0.003 |
| $\eta$ for Hessian inverse estimation | 0.5 | 0.5 | 0.5 | 0.5 |
| $Q$ for Hessian inverse estimation | 3 | 3 | 3 | 3 |

## C Supporting Lemmas

In this section, we provide some auxiliary lemmas used for proving the main convergence results.
First note that the Lipschitz properties in Assumption 2 imply the following lemma.
Lemma 1. Suppose Assumption 2 holds. Then, the stochastic derivatives $\nabla F(z ; \xi), \nabla G(z ; \xi), \nabla_{x} \nabla_{y} G(z ; \xi)$ and $\nabla_{y}^{2} G(z ; \xi)$ have bounded variances, i.e., for any $z$ and $\xi$,

- $\mathbb{E}_{\xi}\|\nabla F(z ; \xi)-\nabla f(z)\|^{2} \leq M^{2}$.
- $\mathbb{E}_{\xi}\left\|\nabla_{x} \nabla_{y} G(z ; \xi)-\nabla_{x} \nabla_{y} g(z)\right\|^{2} \leq L^{2}$.
- $\mathbb{E}_{\xi}\left\|\nabla_{y}^{2} G(z ; \xi)-\nabla_{y}^{2} g(z)\right\|^{2} \leq L^{2}$.

Recall the function $\Phi(x)=f\left(x, y^{*}(x)\right)$ in eq. (2). Then, we use the following lemma to characterize the Lipschitz properties of the gradient $\nabla \Phi(x)$, which is adapted from Lemma 2.2 in Ghadimi and Wang (2018).

Lemma 2. Suppose Assumptions 1, 2 and 3 hold. Then, we have, for any $x, x^{\prime} \in \mathbb{R}^{p}$,

$$
\left\|\nabla \Phi(x)-\nabla \Phi\left(x^{\prime}\right)\right\| \leq L_{\Phi}\left\|x-x^{\prime}\right\|
$$

where the constant $L_{\Phi}$ is given by

$$
\begin{equation*}
L_{\Phi}=L+\frac{2 L^{2}+\tau M^{2}}{\mu}+\frac{\rho L M+L^{3}+\tau M L}{\mu^{2}}+\frac{\rho L^{2} M}{\mu^{3}} . \tag{11}
\end{equation*}
$$

## D Proof of Propositions in Section 2

In this section, we provide the proofs for Proposition 1 and Proposition 2 in Section 2,

## D. 1 Proof of Proposition 1

Based on the iterative update of line 5 in Algorithm 1, we have $y_{k}^{T}=y_{k}^{0}-\alpha \sum_{t=0}^{T-1} \nabla_{y} g\left(x_{k}, y_{k}^{t}\right)$, which, combined with the fact that $\nabla_{y} g\left(x_{k}, y_{k}^{t}\right)$ is differentiable w.r.t. $x_{k}$, indicates that the inner output $y_{k}^{T}$ is differentiable w.r.t. $x_{k}$. Then, based on the chain rule, we have

$$
\begin{equation*}
\frac{\partial f\left(x_{k}, y_{k}^{T}\right)}{\partial x_{k}}=\nabla_{x} f\left(x_{k}, y_{k}^{T}\right)+\frac{\partial y_{k}^{T}}{\partial x_{k}} \nabla_{y} f\left(x_{k}, y_{k}^{T}\right) \tag{12}
\end{equation*}
$$

Based on the iterative updates that $y_{k}^{t}=y_{k}^{t-1}-\alpha \nabla_{y} g\left(x_{k}, y_{k}^{t-1}\right)$ for $t=1, \ldots, T$, we have

$$
\begin{aligned}
\frac{\partial y_{k}^{t}}{\partial x_{k}} & =\frac{\partial y_{k}^{t-1}}{\partial x_{k}}-\alpha \nabla_{x} \nabla_{y} g\left(x_{k}, y_{k}^{t-1}\right)-\alpha \frac{\partial y_{k}^{t-1}}{\partial x_{k}} \nabla_{y}^{2} g\left(x_{k}, y_{k}^{t-1}\right) \\
& =\frac{\partial y_{k}^{t-1}}{\partial x_{k}}\left(I-\alpha \nabla_{y}^{2} g\left(x_{k}, y_{k}^{t-1}\right)\right)-\alpha \nabla_{x} \nabla_{y} g\left(x_{k}, y_{k}^{t-1}\right)
\end{aligned}
$$

Telescoping the above equality over $t$ from 1 to $T$ yields

$$
\begin{align*}
& \frac{\partial y_{k}^{T}}{\partial x_{k}}=\frac{\partial y_{k}^{0}}{\partial x_{k}} \prod_{t=0}^{T-1}\left(I-\alpha \nabla_{y}^{2} g\left(x_{k}, y_{k}^{t}\right)\right)-\alpha \sum_{t=0}^{T-1} \nabla_{x} \nabla_{y} g\left(x_{k}, y_{k}^{t}\right) \prod_{j=t+1}^{T-1}\left(I-\alpha \nabla_{y}^{2} g\left(x_{k}, y_{k}^{j}\right)\right) \\
& \quad \stackrel{(i)}{=}-\alpha \sum_{t=0}^{T-1} \nabla_{x} \nabla_{y} g\left(x_{k}, y_{k}^{t}\right) \prod_{j=t+1}^{T-1}\left(I-\alpha \nabla_{y}^{2} g\left(x_{k}, y_{k}^{j}\right)\right) . \tag{13}
\end{align*}
$$

where $(i)$ follows from the fact that $\frac{\partial y_{k}^{0}}{\partial x_{k}}=0$. Then, combining eq. 12 and eq. 13 completes the proof.

## D. 2 Proof of Proposition 2

Using the chain rule over the gradient $\nabla \Phi\left(x_{k}\right)=\frac{\partial f\left(x_{k}, y^{*}\left(x_{k}\right)\right)}{\partial x_{k}}$, we have

$$
\begin{equation*}
\nabla \Phi\left(x_{k}\right)=\nabla_{x} f\left(x_{k}, y^{*}\left(x_{k}\right)\right)+\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}} \nabla_{y} f\left(x_{k}, y^{*}\left(x_{k}\right)\right) \tag{14}
\end{equation*}
$$

Based on the optimality of $y^{*}\left(x_{k}\right)$, we have $\nabla_{y} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)=0$, which, using the implicit differentiation w.r.t. $x_{k}$, yields

$$
\nabla_{x} \nabla_{y} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)+\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}} \nabla_{y}^{2} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)=0
$$

which implies

$$
\begin{equation*}
\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}=-\nabla_{x} \nabla_{y} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)\left(\nabla_{y}^{2} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)\right)^{-1} \tag{15}
\end{equation*}
$$

Combining eq. 15 and eq. 14 finishes the proof.

## E Proof of Main Results for Deterministic Case in Section 4.1

## E. 1 Proof of Proposition 3

Based on eq. 12 and $\nabla \Phi\left(x_{k}\right)=\nabla_{x} f\left(x_{k}, y^{*}\left(x_{k}\right)\right)+\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}} \nabla_{y} f\left(x_{k}, y^{*}\left(x_{k}\right)\right)$, and using the triangle inequality, we have

$$
\begin{align*}
& \| \frac{\partial f\left(x_{k}, y_{k}^{T}\right)}{\partial x_{k}}-\nabla \Phi\left(x_{k}\right) \| \\
&=\left\|\nabla_{x} f\left(x_{k}, y_{k}^{T}\right)-\nabla_{x} f\left(x_{k}, y^{*}\left(x_{k}\right)\right)\right\|+\left\|\frac{\partial y_{k}^{T}}{\partial x_{k}}-\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}\right\|\left\|\nabla_{y} f\left(x_{k}, y_{k}^{T}\right)\right\| \\
&+\left\|\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}\right\|\left\|\nabla_{y} f\left(x_{k}, y_{k}^{T}\right)-\nabla_{y} f\left(x_{k}, y^{*}\left(x_{k}\right)\right)\right\| \\
& \quad \stackrel{(i)}{\leq} L\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|+M\left\|\frac{\partial y_{k}^{T}}{\partial x_{k}}-\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}\right\|+L\left\|\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}\right\|\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\| \tag{16}
\end{align*}
$$

where ( $i$ ) follows from Assumption 2. Our next step is to upper-bound $\left\|\frac{\partial y_{k}^{T}}{\partial x_{k}}-\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}\right\|$ in eq. 16.
Based on the updates $y_{k}^{t}=y_{k}^{t-1}-\alpha \nabla_{y} g\left(x_{k}, y_{k}^{t-1}\right)$ for $t=1, \ldots, T$ in Algorithm 1 and using the chain rule, we have

$$
\begin{equation*}
\frac{\partial y_{k}^{t}}{\partial x_{k}}=\frac{\partial y_{k}^{t-1}}{\partial x_{k}}-\alpha\left(\nabla_{x} \nabla_{y} g\left(x_{k}, y_{k}^{t-1}\right)+\frac{\partial y_{k}^{t-1}}{\partial x_{k}} \nabla_{y}^{2} g\left(x_{k}, y_{k}^{t-1}\right)\right) \tag{17}
\end{equation*}
$$

Based on the optimality of $y^{*}\left(x_{k}\right)$, we have $\nabla_{y} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)=0$, which, in conjunction with the implicit differentiation theorem, yields

$$
\begin{equation*}
\nabla_{x} \nabla_{y} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)+\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}} \nabla_{y}^{2} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)=0 \tag{18}
\end{equation*}
$$

Substituting eq. (18) into eq. 17 yields

$$
\begin{align*}
\frac{\partial y_{k}^{t}}{\partial x_{k}} & -\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}} \\
= & \frac{\partial y_{k}^{t-1}}{\partial x_{k}}-\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}-\alpha\left(\nabla_{x} \nabla_{y} g\left(x_{k}, y_{k}^{t-1}\right)+\frac{\partial y_{k}^{t-1}}{\partial x_{k}} \nabla_{y}^{2} g\left(x_{k}, y_{k}^{t-1}\right)\right) \\
& +\alpha\left(\nabla_{x} \nabla_{y} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)+\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}} \nabla_{y}^{2} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)\right) \\
= & \frac{\partial y_{k}^{t-1}}{\partial x_{k}}-\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}-\alpha\left(\nabla_{x} \nabla_{y} g\left(x_{k}, y_{k}^{t-1}\right)-\nabla_{x} \nabla_{y} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)\right) \\
& -\alpha\left(\frac{\partial y_{k}^{t-1}}{\partial x_{k}}-\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}\right) \nabla_{y}^{2} g\left(x_{k}, y_{k}^{t-1}\right) \\
& +\alpha \frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}\left(\nabla_{y}^{2} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)-\nabla_{y}^{2} g\left(x_{k}, y_{k}^{t-1}\right)\right) . \tag{19}
\end{align*}
$$

Combining eq. 18 and Assumption 2 yields

$$
\begin{equation*}
\left\|\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}\right\|=\left\|\nabla_{x} \nabla_{y} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)\left[\nabla_{y}^{2} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)\right]^{-1}\right\| \leq \frac{L}{\mu} \tag{20}
\end{equation*}
$$

Then, combining eq. 19) and eq. 20 yields

$$
\begin{align*}
\left\|\frac{\partial y_{k}^{t}}{\partial x_{k}}-\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}\right\| \stackrel{(i)}{\leq} & \left\|I-\alpha \nabla_{y}^{2} g\left(x_{k}, y_{k}^{t-1}\right)\right\|\left\|\frac{\partial y_{k}^{t-1}}{\partial x_{k}}-\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}\right\| \\
& +\alpha\left(\tau+\frac{L \rho}{\mu}\right)\left\|y_{k}^{t-1}-y^{*}\left(x_{k}\right)\right\| \\
& \stackrel{(i i)}{\leq}(1-\alpha \mu)\left\|\frac{\partial y_{k}^{t-1}}{\partial x_{k}}-\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}\right\|+\alpha\left(\tau+\frac{L \rho}{\mu}\right)\left\|y_{k}^{t-1}-y^{*}\left(x_{k}\right)\right\|, \tag{21}
\end{align*}
$$

where $(i)$ follows from Assumption 3 and (ii) follows from the strong-convexity of $g(x, \cdot)$. Based on the strong-convexity of the lower-level function $g(x, \cdot)$, we have

$$
\begin{equation*}
\left\|y_{k}^{t-1}-y^{*}\left(x_{k}\right)\right\| \leq(1-\alpha \mu)^{\frac{t-1}{2}}\left\|y_{k}^{0}-y^{*}\left(x_{k}\right)\right\| \tag{22}
\end{equation*}
$$

Substituting eq. (22) into eq. 21) and telecopting eq. 21) over $t$ from 1 to $T$, we have

$$
\begin{align*}
\left\|\frac{\partial y_{k}^{T}}{\partial x_{k}}-\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}\right\| \leq & (1-\alpha \mu)^{T}\left\|\frac{\partial y_{k}^{0}}{\partial x_{k}}-\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}\right\| \\
& +\alpha\left(\tau+\frac{L \rho}{\mu}\right) \sum_{t=0}^{T-1}(1-\alpha \mu)^{T-1-t}(1-\alpha \mu)^{\frac{t}{2}}\left\|y_{k}^{0}-y^{*}\left(x_{k}\right)\right\| \\
= & (1-\alpha \mu)^{T}\left\|\frac{\partial y_{k}^{0}}{\partial x_{k}}-\frac{\partial y^{*}\left(x_{k}\right)}{\partial x_{k}}\right\|+\frac{2(\tau \mu+L \rho)}{\mu^{2}}(1-\alpha \mu)^{\frac{T-1}{2}}\left\|y_{k}^{0}-y^{*}\left(x_{k}\right)\right\| \\
\leq & \frac{L(1-\alpha \mu)^{T}}{\mu}+\frac{2(\tau \mu+L \rho)}{\mu^{2}}(1-\alpha \mu)^{\frac{T-1}{2}}\left\|y_{k}^{0}-y^{*}\left(x_{k}\right)\right\|, \tag{23}
\end{align*}
$$

where the last inequality follows from $\frac{\partial y_{k}^{0}}{\partial x_{k}}=0$ and eq. 20. Then, combining eq. 16. eq. 20. eq. 22. and eq. (23) completes the proof.

## E. 2 Proof of Theorem 1

Based on the characterization on the estimation error of the gradient estimate $\frac{\partial f\left(x_{k}, y_{k}^{T}\right)}{\partial x_{k}}$ in Proposition 3 we now prove Theorem 1 .

To simplify notations, we let $\widehat{\nabla} \Phi\left(x_{k}\right)=\frac{\partial f\left(x_{k}, y_{k}^{T}\right)}{\partial x_{k}}$. Based on the smoothness of the function $\Phi(x)$ established in Lemma 2, we have

$$
\begin{align*}
\Phi\left(x_{k+1}\right) \leq & \Phi\left(x_{k}\right)+\left\langle\nabla \Phi\left(x_{k}\right), x_{k+1}-x_{k}\right\rangle+\frac{L_{\Phi}}{2}\left\|x_{k+1}-x_{k}\right\|^{2} \\
\leq & \Phi\left(x_{k}\right)-\beta\left\langle\nabla \Phi\left(x_{k}\right), \widehat{\nabla} \Phi\left(x_{k}\right)-\nabla \Phi\left(x_{k}\right)\right\rangle-\beta\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2}+\beta^{2} L_{\Phi}\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2} \\
& +\beta^{2} L_{\Phi}\left\|\nabla \Phi\left(x_{k}\right)-\widehat{\nabla} \Phi\left(x_{k}\right)\right\|^{2} \\
\leq & \Phi\left(x_{k}\right)-\left(\frac{\beta}{2}-\beta^{2} L_{\Phi}\right)\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2}+\left(\frac{\beta}{2}+\beta^{2} L_{\Phi}\right)\left\|\nabla \Phi\left(x_{k}\right)-\widehat{\nabla} \Phi\left(x_{k}\right)\right\|^{2}, \tag{24}
\end{align*}
$$

which, in conjunction with Proposition 3 and use $\left\|y_{k}^{0}-y^{*}\left(x_{k}\right)\right\|^{2} \leq \Delta$, yields

$$
\begin{align*}
\Phi\left(x_{k+1}\right) \leq & \Phi\left(x_{k}\right)-\left(\frac{\beta}{2}-\beta^{2} L_{\Phi}\right)\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2} \\
& +3 \Delta\left(\frac{\beta}{2}+\beta^{2} L_{\Phi}\right)\left(\frac{L^{2}(L+\mu)^{2}}{\mu^{2}}(1-\alpha \mu)^{T}+\frac{4 M^{2}(\tau \mu+L \rho)^{2}}{\mu^{4}}(1-\alpha \mu)^{T-1}\right) \\
& +3\left(\frac{\beta}{2}+\beta^{2} L_{\Phi}\right) \frac{L^{2} M^{2}(1-\alpha \mu)^{2 T}}{\mu^{2}} . \tag{25}
\end{align*}
$$

Telescoping eq. 25 over $k$ from 0 to $K-1$ yields

$$
\begin{align*}
& \frac{1}{K} \sum_{k=0}^{K-1}\left(\frac{1}{2}-\beta L_{\Phi}\right)\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2} \leq \frac{\Phi\left(x_{0}\right)-\inf _{x} \Phi(x)}{\beta K}+3\left(\frac{1}{2}+\beta L_{\Phi}\right) \frac{L^{2} M^{2}(1-\alpha \mu)^{2 T}}{\mu^{2}} \\
& \quad+3 \Delta\left(\frac{1}{2}+\beta L_{\Phi}\right)\left(\frac{L^{2}(L+\mu)^{2}}{\mu^{2}}(1-\alpha \mu)^{T}+\frac{4 M^{2}(\tau \mu+L \rho)^{2}}{\mu^{4}}(1-\alpha \mu)^{T-1}\right) \tag{26}
\end{align*}
$$

Substuting $\beta=\frac{1}{4 L_{\Phi}}$ and $T=\log \left(\max \left\{\frac{3 L M}{\mu}, 9 \Delta L^{2}\left(1+\frac{L}{\mu}\right)^{2}, \frac{36 \Delta M^{2}(\tau \mu+L \rho)^{2}}{(1-\alpha \mu) \mu^{4}}\right\} \frac{9}{2 \epsilon}\right) / \log \frac{1}{1-\alpha \mu}=\Theta\left(\kappa \log \frac{1}{\epsilon}\right)$ in eq. (26) yields

$$
\begin{equation*}
\frac{1}{K} \sum_{k=0}^{K-1}\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2} \leq \frac{16 L_{\Phi}\left(\Phi\left(x_{0}\right)-\inf _{x} \Phi(x)\right)}{K}+\frac{2 \epsilon}{3} \tag{27}
\end{equation*}
$$

In order to achieve an $\epsilon$-accurate stationary point, we obtain from eq. 27, that Algorithm 1 requires at most the total number $K=\mathcal{O}\left(\kappa^{3} \epsilon^{-1}\right)$ of outer iterations. Then, based on the gradient form given by Proposition 1 , we have the following complexity results.

- Gradient complexity:

$$
\operatorname{Gc}(f, \epsilon)=2 K=\mathcal{O}\left(\kappa^{3} \epsilon^{-1}\right), \operatorname{Gc}(g, \epsilon)=K T=\mathcal{O}\left(\kappa^{4} \epsilon^{-1} \log \frac{1}{\epsilon}\right)
$$

- High-order derivative complexity:

$$
\operatorname{Hxy}(g, \epsilon)=K T=\mathcal{O}\left(\kappa^{4} \epsilon^{-1} \log \frac{1}{\epsilon}\right), \operatorname{Hyy}(g, \epsilon)=K T=\mathcal{O}\left(\kappa^{4} \epsilon^{-1} \log \frac{1}{\epsilon}\right)
$$

Then, the proof is complete.

## F Proofs of Main Results for Stochastic Case in Section 4.2

In this section, we provide proofs for the convergence and complexity results of the proposed algorithm for the stochastic case.

## F. 1 Proof of Proposition 4

Based on the definition of $H^{\text {inv }}\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{H}\right)$ in eq. (5), we have

$$
\begin{aligned}
\mathbb{E}_{\mathcal{D}_{H}} H^{\text {inv }}\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{H}\right)= & \mathbb{E}_{\mathcal{D}_{H}}\left(\eta \sum_{q=0}^{Q} \prod_{j=1}^{q}\left(I-\eta \nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{j}\right)\right)\right) \\
& =\eta \sum_{q=0}^{Q}\left(I-\eta \nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right)^{q} \\
& =\eta \sum_{q=0}^{\infty}\left(I-\eta \nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right)^{q}-\eta \sum_{q=Q+1}^{\infty}\left(I-\eta \nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right)^{q} \\
& =\eta\left(\eta \nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right)^{-1}-\eta \sum_{q=Q+1}^{\infty}\left(I-\eta \nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right)^{q},
\end{aligned}
$$

which, in conjunction with the strong-convexity of function $g(x, \cdot)$, yields

$$
\begin{equation*}
\left\|\mathbb{E}_{\mathcal{D}_{H}} H^{\mathrm{inv}}\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{H}\right)-\left[\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right]^{-1}\right\| \leq \eta \sum_{q=Q+1}^{\infty}(1-\eta \mu)^{q} \leq \frac{(1-\eta \mu)^{Q+1}}{\mu} \tag{28}
\end{equation*}
$$

This finishes the proof for the estimation bias. We next prove the variance bound. Note that

$$
\begin{align*}
& \mathbb{E}_{\mathcal{D}_{H}}\left\|\eta \sum_{q=0}^{Q} \prod_{j=1}^{q}\left(I-\eta \nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{j}\right)\right)-\left(\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right)^{-1}\right\|^{2} \\
& \quad \leq 2 \mathbb{E}_{\mathcal{D}_{H}}\left\|\eta \sum_{q=0}^{Q} \prod_{j=1}^{q}\left(I-\eta \nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{j}\right)\right)-\eta \sum_{q=0}^{Q}\left(I-\eta \nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right)^{q}\right\|^{2} \\
& \left.\quad+2 \mathbb{E}_{\mathcal{D}_{H}} \| \eta \prod_{q=0}^{Q}\left(I-\eta \nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right)^{q}\right)-\left(\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right)^{-1} \|^{2} \\
& \quad{ }^{(i)} \leq 2 \eta^{2} \mathbb{E}_{\mathcal{D}_{H}}\left\|\sum_{q=0}^{Q} \prod_{j=1}^{q}\left(I-\eta \nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{j}\right)\right)-\sum_{q=0}^{Q}\left(I-\eta \nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right)^{q}\right\|^{2}+\frac{2(1-\eta \mu)^{2 Q+2}}{\mu^{2}} \\
& \quad{ }_{M_{q}}^{(i i)} \leq 2 \eta^{2} Q \mathbb{E}_{\mathcal{D}_{H}} \sum_{q=0}^{Q} \underbrace{\prod_{j=1}^{q}\left(I-\eta \nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{j}\right)\right)-\left(I-\eta \nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right)^{q} \|^{2}}+\frac{2(1-\eta \mu)^{2 Q+2}}{\mu^{2}} \tag{29}
\end{align*}
$$

where ( $i$ ) follows from eq. 28, and ( $i$ ii) follows from the Cauchy-Schwarz inequality.
Our next step is to upper-bound $M_{q}$ in eq. 29 . For simplicity, we define a general quantity $M_{i}$ for by replacing $q$ in $M_{q}$ with $i$. Then, we have

$$
\begin{align*}
& \mathbb{E}_{\mathcal{D}_{H}} M_{i}= \mathbb{E}_{\mathcal{D}_{H}} \| \prod_{j=1}^{i-1}\left(I-\eta \nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{j}\right)\right)\left(I-\eta \nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)-\left(I-\eta \nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right)^{i} \|^{2}\right. \\
&+\mathbb{E}_{\mathcal{D}_{H}}\left\|\prod_{j=1}^{i-1}\left(I-\eta \nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{j}\right)\right) \eta\left(\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)-\nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{i}\right)\right)\right\|^{2} \\
&+2 \mathbb{E}_{\mathcal{D}_{H}}\left\langle\prod _ { j = 1 } ^ { i - 1 } ( I - \eta \nabla _ { y } ^ { 2 } G ( x _ { k } , y _ { k } ^ { T } ; \mathcal { B } _ { j } ) ) \left( I-\eta \nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)-\left(I-\eta \nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right)^{i},\right.\right. \\
& \quad\left.\quad \prod_{j=1}^{i-1}\left(I-\eta \nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{j}\right)\right) \eta\left(\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)-\nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{i}\right)\right)\right\rangle \\
&+\mathbb{E}_{\mathcal{D}_{H}} \| \prod_{j=1}^{i-1}\left(I-\eta \nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{j}\right)\right)\left(I-\eta \nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)-\left(I-\eta \nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right)^{i} \|^{2}\right. \\
&\left\|\prod_{\mathcal{D}_{H}}^{i-1}\left(I-\eta \nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{j}\right)\right) \eta\left(\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)-\nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{i}\right)\right)\right\|^{2} \\
& \quad(i i) \\
& \leq(1-\eta \mu)^{2} \mathbb{E}_{\mathcal{D}_{H}} M_{i-1}+\eta^{2}(1-\eta \mu)^{2 i-2} \mathbb{E}_{\mathcal{D}_{H}}\left\|\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)-\nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{i}\right)\right\|^{2}  \tag{30}\\
& \quad(i i i) \\
& \leq(1-\eta \mu)^{2} \mathbb{E}_{\mathcal{D}_{H}} M_{i-1}+\eta^{2}(1-\eta \mu)^{2 i-2} \frac{L^{2}}{\left|\mathcal{B}_{i}\right|},
\end{align*}
$$

where $(i)$ follows from that fact that $\mathbb{E}_{\mathcal{B}_{i}} \nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{i}\right)=\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)$, (ii) follows from the strong-convexity of function $G(x, \cdot ; \xi)$, and (iii) follows from Lemma 1 .

Then, telescoping eq. 30 over $i$ from 2 to $q$ yields

$$
\mathbb{E}_{\mathcal{D}_{H}} M_{q} \leq L^{2} \eta^{2}(1-\eta \mu)^{2 q-2} \sum_{j=1}^{q} \frac{1}{\left|\mathcal{B}_{j}\right|}
$$

which, in conjunction with the choice of $\left|\mathcal{B}_{j}\right|=B Q(1-\eta \mu)^{j-1}$ for $j=1, \ldots, Q$, yields

$$
\begin{align*}
\mathbb{E}_{\mathcal{D}_{H}} M_{q} & \leq \eta^{2}(1-\eta \mu)^{2 q-2} \sum_{j=1}^{q} \frac{L^{2}}{B Q}\left(\frac{1}{1-\eta \mu}\right)^{j-1} \\
& =\frac{\eta^{2} L^{2}}{B Q}(1-\eta \mu)^{2 q-2} \frac{\left(\frac{1}{1-\eta \mu}\right)^{q-1}-1}{\frac{1}{1-\eta \mu}-1} \leq \frac{\eta L^{2}}{(1-\eta \mu) \mu} \frac{1}{B Q}(1-\eta \mu)^{q} . \tag{31}
\end{align*}
$$

Substituting eq. (31) into eq. 29) yields

$$
\begin{align*}
& \mathbb{E}_{\mathcal{D}_{H}}\left\|\eta \sum_{q=0}^{Q} \prod_{j=1}^{q}\left(I-\eta \nabla_{y}^{2} G\left(x_{k}, y_{k}^{T} ; \mathcal{B}_{j}\right)\right)-\left(\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right)^{-1}\right\|^{2} \\
& \quad \leq \frac{2 \eta^{3} L^{2}}{\mu} \frac{1}{B} \sum_{q=0}^{Q}(1-\eta \mu)^{q}+\frac{2(1-\eta \mu)^{2 Q+2}}{\mu^{2}} \\
& \quad \leq \frac{2 \eta^{2} L^{2}}{\mu^{2}} \frac{1}{B}+\frac{2(1-\eta \mu)^{2 Q+2}}{\mu^{2}} \tag{32}
\end{align*}
$$

where the last inequality follows from the fact that $\sum_{q=0}^{S} x^{q} \leq \frac{1}{1-x}$. Then, the proof is complete.

## F. 2 Auxiliary Lemmas for Proving Theorem 2

We first use the following lemma to characterize the first-moment error of the gradient estimate $\widehat{\nabla} \Phi\left(x_{k}\right)$, whose form is given by eq. (3).
Lemma 3. Suppose Assumptions 1. 2 and 3 hold. Then, conditioning on $x_{k}$ and $y_{k}^{T}$, we have

$$
\left\|\mathbb{E} \widehat{\nabla} \Phi\left(x_{k}\right)-\nabla \Phi\left(x_{k}\right)\right\|^{2} \leq 2\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2}\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|^{2}+\frac{2 L^{2} M^{2}(1-\eta \mu)^{2 Q}}{\mu^{2}}
$$

Proof of Lemma 3. To simplify notations, we define

$$
\begin{equation*}
\widetilde{\nabla} \Phi_{T}\left(x_{k}\right)=\nabla_{x} f\left(x_{k}, y_{k}^{T}\right)-\nabla_{x} \nabla_{y} g\left(x_{k}, y_{k}^{T}\right)\left[\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right]^{-1} \nabla_{y} f\left(x_{k}, y_{k}^{T}\right) \tag{33}
\end{equation*}
$$

Based on the definition of $\nabla \Phi\left(x_{k}\right)$ in eq. (3) and conditioning on $x_{k}$ and $y_{k}^{T}$, we have

$$
\begin{aligned}
\mathbb{E} \widehat{\nabla} \Phi\left(x_{k}\right) & =\nabla_{x} f\left(x_{k}, y_{k}^{T}\right)-\nabla_{x} \nabla_{y} g\left(x_{k}, y_{k}^{T}\right)\left[\mathbb{E} H^{\mathrm{inv}}\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{H}\right)\right] \nabla_{y} f\left(x_{k}, y_{k}^{T}\right) \\
& =\widetilde{\nabla} \Phi_{T}\left(x_{k}\right)+\nabla_{x} \nabla_{y} g\left(x_{k}, y_{k}^{T}\right)\left(\left[\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right]^{-1}-\mathbb{E} H^{\mathrm{inv}}\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{H}\right)\right) \nabla_{y} f\left(x_{k}, y_{k}^{T}\right),
\end{aligned}
$$

which further implies that

$$
\begin{align*}
& \| \mathbb{E} \widehat{\nabla} \Phi\left(x_{k}\right)-\nabla \Phi\left(x_{k}\right) \|^{2} \\
& \quad \leq 2 \mathbb{E}\left\|\widetilde{\nabla} \Phi_{T}\left(x_{k}\right)-\nabla \Phi\left(x_{k}\right)\right\|^{2}+2\left\|\mathbb{E} \hat{\nabla} \Phi\left(x_{k}\right)-\widetilde{\nabla} \Phi_{T}\left(x_{k}\right)\right\|^{2} \\
& \leq 2 \mathbb{E}\left\|\widetilde{\nabla} \Phi_{T}\left(x_{k}\right)-\nabla \Phi\left(x_{k}\right)\right\|^{2}+2 L^{2} M^{2}\left\|\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)^{-1}-\mathbb{E} H^{\mathrm{inv}}\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{H}\right)\right\|^{2} \\
& \leq 2 \mathbb{E}\left\|\widetilde{\nabla} \Phi_{T}\left(x_{k}\right)-\nabla \Phi\left(x_{k}\right)\right\|^{2}+\frac{2 L^{2} M^{2}(1-\eta \mu)^{2 Q}}{\mu^{2}} \tag{34}
\end{align*}
$$

where the last inequality follows from Proposition 4. Our next step is to upper-bound the first term at the right hand side of eq. (34). Using the fact that $\left\|\nabla_{y}^{2} g(x, y)^{-1}\right\| \leq \frac{1}{\mu}$ and based on Assumptions 2 and 3 , we have

$$
\begin{align*}
\left\|\widetilde{\nabla} \Phi_{T}\left(x_{k}\right)-\nabla \Phi\left(x_{k}\right)\right\| \leq & \left\|\nabla_{x} f\left(x_{k}, y_{k}^{T}\right)-\nabla_{x} f\left(x_{k}, y^{*}\left(x_{k}\right)\right)\right\| \\
& +\frac{L^{2}}{\mu}\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|+\frac{M \tau}{\mu}\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\| \\
& +L M\left\|\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)^{-1}-\nabla_{y}^{2} g\left(x_{k}, y^{*}\left(x_{k}\right)\right)^{-1}\right\| \\
\leq & \left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\| \tag{35}
\end{align*}
$$

where the last inequality follows from the inequality $\left\|M_{1}^{-1}-M_{2}^{-1}\right\| \leq\left\|M_{1}^{-1} M_{2}^{-1}\right\|\left\|M_{1}-M_{2}\right\|$ for any two matrices $M_{1}$ and $M_{2}$. Combining eq. (34) and eq. (35) yields

$$
\left\|\mathbb{E} \widehat{\nabla} \Phi\left(x_{k}\right)-\nabla \Phi\left(x_{k}\right)\right\|^{2} \leq 2\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2}\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|^{2}+\frac{2 L^{2} M^{2}(1-\eta \mu)^{2 Q}}{\mu^{2}}
$$

which completes the proof.
Then, we use the following lemma to characterize the variance of the estimator $\widehat{\nabla} \Phi\left(x_{k}\right)$.
Lemma 4. Suppose Assumptions 1, 2 and 3 hold. Then, we have

$$
\begin{aligned}
\mathbb{E}\left\|\widehat{\nabla} \Phi\left(x_{k}\right)-\nabla \Phi\left(x_{k}\right)\right\|^{2} \leq & \frac{6 L^{2} M^{2}}{\mu^{2} D_{g}}+\left(\frac{6 L^{2}}{\mu^{2}}+2\right) \frac{M^{2}}{D_{f}}+\frac{12 \eta^{2} L^{4} M^{2}}{\mu^{2}} \frac{1}{B}+\frac{12 L^{2} M^{2}(1-\eta \mu)^{2 Q+2}}{\mu^{2}} \\
& +\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2} \mathbb{E}\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|^{2} .
\end{aligned}
$$

Proof of Lemma 4. Based on the definitions of $\nabla \Phi\left(x_{k}\right)$ and $\widetilde{\nabla} \Phi_{T}\left(x_{k}\right)$ in eq. (3) and eq. 33) and conditioning on $x_{k}$ and $y_{k}^{T}$, we have

$$
\begin{align*}
& \mathbb{E}\left\|\widehat{\nabla} \Phi\left(x_{k}\right)-\nabla \Phi\left(x_{k}\right)\right\|^{2} \\
& \stackrel{(i)}{=} \mathbb{E}\left\|\widehat{\nabla} \Phi\left(x_{k}\right)-\widetilde{\nabla} \Phi_{T}\left(x_{k}\right)\right\|^{2}+\left\|\widetilde{\nabla} \Phi_{T}\left(x_{k}\right)-\nabla \Phi\left(x_{k}\right)\right\|^{2} \\
& \stackrel{(i i)}{\leq} 2 \mathbb{E} \| \nabla_{x} \nabla_{y} G\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{G}\right) H^{\mathrm{inv}}\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{H}\right) \nabla_{y} F\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{F}\right) \\
& -\nabla_{x} \nabla_{y} g\left(x_{k}, y_{k}^{T}\right)\left[\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)\right]^{-1} \nabla_{y} f\left(x_{k}, y_{k}^{T}\right) \|^{2}+\frac{2 M^{2}}{D_{f}} \\
& +\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2}\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|^{2} \\
& \stackrel{(i i i)}{\leq} 6 M^{2} \mathbb{E}\left\|\nabla_{x} \nabla_{y} G\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{G}\right)-\nabla_{x} \nabla_{y} g\left(x_{k}, y_{k}^{T}\right)\right\|^{2}\left\|H^{\mathrm{inv}}\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{H}\right)\right\|^{2} \\
& +6 L^{2} M^{2} \mathbb{E}\left\|H^{\mathrm{inv}}\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{H}\right)-\nabla_{y}^{2} g\left(x_{k}, y_{k}^{T}\right)^{-1}\right\|^{2}+\frac{6 L^{2}}{\mu^{2}}\left\|\nabla_{y} F\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{F}\right)-\nabla_{y} f\left(x_{k}, y_{k}^{T}\right)\right\|^{2} \\
& +\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2}\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|^{2}+\frac{2 M^{2}}{D_{f}}, \tag{36}
\end{align*}
$$

where ( $i$ ) follows from the fact that $\mathbb{E}_{\mathcal{D}_{G}, \mathcal{D}_{H}, \mathcal{D}_{F}} \widehat{\nabla} \Phi\left(x_{k}\right)=\widetilde{\nabla} \Phi_{T}\left(x_{k}\right)$, (ii) follows from Lemma 1 and eq. 35), and (iii) follows from the Young's inequality and Assumption 2 . Note that

$$
\left\|H^{\mathrm{inv}}\left(x_{k}, y_{k}^{T} ; \mathcal{D}_{H}\right)\right\| \leq \eta \sum_{q=0}^{Q}(1-\eta \mu)^{q}=\frac{1-(1-\eta \mu)^{Q+1}}{\mu} \leq \frac{1}{\mu}
$$

which, in conjunction with eq. 36) and using Lemma 1 and Proposition 4, yields

$$
\begin{align*}
\mathbb{E}\left\|\widehat{\nabla} \Phi\left(x_{k}\right)-\nabla \Phi\left(x_{k}\right)\right\|^{2} \leq & \frac{6 L^{2} M^{2}}{\mu^{2} D_{g}}+\frac{6 L^{2} M^{2}}{\mu^{2} D_{f}}+6 L^{2} M^{2}\left(\frac{2 \eta^{2} L^{2}}{\mu^{2}} \frac{1}{B}+\frac{2(1-\eta \mu)^{2 Q+2}}{\mu^{2}}\right) \\
& +\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2}\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|^{2}+\frac{2 M^{2}}{D_{f}} \tag{37}
\end{align*}
$$

which, unconditioning on $x_{k}$ and $y_{k}^{T}$, completes the proof.
It can be seen from Lemmas 3 and 4 that the upper bounds on both the estimation error and bias depend on the tracking error $\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|^{2}$. The following lemma provides an upper bound on such tracking error $\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|^{2}$.
Lemma 5. Suppose Assumptions 1, 2 and 4 hold. Define constants

$$
\begin{align*}
& \lambda=\left(\frac{L-\mu}{L+\mu}\right)^{2 T}\left(2+\frac{8 \beta^{2} L^{2}}{\mu^{2}}\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2}\right) \\
& \Delta=\frac{6 L^{2} M^{2}}{\mu^{2} D_{g}}+\left(\frac{6 L^{2}}{\mu^{2}}+2\right) \frac{M^{2}}{D_{f}}+\frac{12 \eta^{2} L^{4} M^{2}}{\mu^{2} B}+\frac{12 L^{2} M^{2}(1-\eta \mu)^{2 Q+2}}{\mu^{2}} \\
& \omega=\frac{4 \beta^{2} L^{2}}{\mu^{2}}\left(\frac{L-\mu}{L+\mu}\right)^{2 T} . \tag{38}
\end{align*}
$$

Choose $T$ such that $\lambda<1$ and set inner-loop stepsize $\alpha=\frac{2}{L+\mu}$. Then, we have

$$
\begin{aligned}
& \mathbb{E}\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|^{2} \\
& \quad \leq \lambda^{k}\left(\left(\frac{L-\mu}{L+\mu}\right)^{2 T}\left\|y_{0}-y^{*}\left(x_{0}\right)\right\|^{2}+\frac{\sigma^{2}}{L \mu S}\right)+\omega \sum_{j=0}^{k-1} \lambda^{k-1-j} \mathbb{E}\left\|\nabla \Phi\left(x_{j}\right)\right\|^{2}+\frac{\omega \Delta+\frac{\sigma^{2}}{L \mu S}}{1-\lambda} .
\end{aligned}
$$

Proof of Lemma 5. First note that for an integer $t \leq T$

$$
\begin{align*}
& \left\|y_{k}^{t+1}-y^{*}\left(x_{k}\right)\right\|^{2} \\
& \quad=\left\|y_{k}^{t+1}-y_{k}^{t}\right\|^{2}+2\left\langle y_{k}^{t+1}-y_{k}^{t}, y_{k}^{t}-y^{*}\left(x_{k}\right)\right\rangle+\left\|y_{k}^{t}-y^{*}\left(x_{k}\right)\right\|^{2} \\
& \quad=\alpha^{2}\left\|\nabla_{y} G\left(x_{k}, y_{k}^{t} ; \mathcal{S}_{t}\right)\right\|^{2}-2 \alpha\left\langle\nabla_{y} G\left(x_{k}, y_{k}^{t} ; \mathcal{S}_{t}\right), y_{k}^{t}-y^{*}\left(x_{k}\right)\right\rangle+\left\|y_{k}^{t}-y^{*}\left(x_{k}\right)\right\|^{2} . \tag{39}
\end{align*}
$$

Conditioning on $y_{k}^{t}$ and taking expectation in eq. 3 , we have

$$
\begin{align*}
& \mathbb{E}\left\|y_{k}^{t+1}-y^{*}\left(x_{k}\right)\right\|^{2} \\
& \quad \stackrel{(i)}{\leq} \alpha^{2}\left(\frac{\sigma^{2}}{S}+\left\|\nabla_{y} g\left(x_{k}, y_{k}^{t}\right)\right\|^{2}\right)-2 \alpha\left\langle\nabla_{y} g\left(x_{k}, y_{k}^{t}\right), y_{k}^{t}-y^{*}\left(x_{k}\right)\right\rangle \\
& \quad+\left\|y_{k}^{t}-y^{*}\left(x_{k}\right)\right\|^{2} \\
& \stackrel{(i i)}{\leq} \\
& \frac{\alpha^{2} \sigma^{2}}{S}+\alpha^{2}\left\|\nabla_{y} g\left(x_{k}, y_{k}^{t}\right)\right\|^{2}-2 \alpha\left(\frac{L \mu}{L+\mu}\left\|y_{k}^{t}-y^{*}\left(x_{k}\right)\right\|^{2}+\frac{\left\|\nabla_{y} g\left(x_{k}, y_{k}^{t}\right)\right\|^{2}}{L+\mu}\right) \\
& \quad+\left\|y_{k}^{t}-y^{*}\left(x_{k}\right)\right\|^{2}  \tag{40}\\
& = \\
& \quad \frac{\alpha^{2} \sigma^{2}}{S}-\alpha\left(\frac{2}{L+\mu}-\alpha\right)\left\|\nabla_{y} g\left(x_{k}, y_{k}^{t}\right)\right\|^{2}+\left(1-\frac{2 \alpha L \mu}{L+\mu}\right)\left\|y_{k}^{t}-y^{*}\left(x_{k}\right)\right\|^{2}
\end{align*}
$$

where ( $i$ ) follows from the third item in Assumption 2 , (ii) follows from the strong-convexity and smoothness of the function $g$. Since $\alpha=\frac{2}{L+\mu}$, we obtain from eq. 40 that

$$
\begin{equation*}
\mathbb{E}\left\|y_{k}^{t+1}-y^{*}\left(x_{k}\right)\right\|^{2} \leq\left(\frac{L-\mu}{L+\mu}\right)^{2}\left\|y_{k}^{t}-y^{*}\left(x_{k}\right)\right\|^{2}+\frac{4 \sigma^{2}}{(L+\mu)^{2} S} \tag{41}
\end{equation*}
$$

Unconditioning on $y_{k}^{t}$ in eq. 41 and telescoping eq. 41 over $t$ from 0 to $T-1$ yields

$$
\begin{align*}
\mathbb{E}\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|^{2} & \leq\left(\frac{L-\mu}{L+\mu}\right)^{2 T} \mathbb{E}\left\|y_{k}^{0}-y^{*}\left(x_{k}\right)\right\|^{2}+\frac{\sigma^{2}}{L \mu S} \\
& =\left(\frac{L-\mu}{L+\mu}\right)^{2 T} \mathbb{E}\left\|y_{k-1}^{T}-y^{*}\left(x_{k}\right)\right\|^{2}+\frac{\sigma^{2}}{L \mu S} \tag{42}
\end{align*}
$$

where the last inequality follows from Algorithm 2 that $y_{k}^{0}=y_{k-1}^{T}$. Note that

$$
\begin{align*}
\mathbb{E}\left\|y_{k-1}^{T}-y^{*}\left(x_{k}\right)\right\|^{2} \leq & 2 \mathbb{E}\left\|y_{k-1}^{T}-y^{*}\left(x_{k-1}\right)\right\|^{2}+2 \mathbb{E}\left\|y^{*}\left(x_{k-1}\right)-y^{*}\left(x_{k}\right)\right\|^{2} \\
\stackrel{(i)}{\leq} & 2 \mathbb{E}\left\|y_{k-1}^{T}-y^{*}\left(x_{k-1}\right)\right\|^{2}+\frac{2 L^{2}}{\mu^{2}} \mathbb{E}\left\|x_{k}-x_{k-1}\right\|^{2} \\
\leq & 2 \mathbb{E}\left\|y_{k-1}^{T}-y^{*}\left(x_{k-1}\right)\right\|^{2}+\frac{2 \beta^{2} L^{2}}{\mu^{2}} \mathbb{E}\left\|\widehat{\nabla} \Phi\left(x_{k-1}\right)\right\|^{2} \\
\leq & 2 \mathbb{E}\left\|y_{k-1}^{T}-y^{*}\left(x_{k-1}\right)\right\|^{2}+\frac{4 \beta^{2} L^{2}}{\mu^{2}} \mathbb{E}\left\|\nabla \Phi\left(x_{k-1}\right)\right\|^{2} \\
& +\frac{4 \beta^{2} L^{2}}{\mu^{2}} \mathbb{E}\left\|\widehat{\nabla} \Phi\left(x_{k-1}\right)-\nabla \Phi\left(x_{k-1}\right)\right\|^{2}, \tag{43}
\end{align*}
$$

where ( $i$ ) follows from Lemma 2.2 in Ghadimi and Wang (2018). Using Lemma 4 in eq. 43) yields

$$
\begin{align*}
& \mathbb{E}\left\|y_{k-1}^{T}-y^{*}\left(x_{k}\right)\right\|^{2} \\
& \leq\left(2+\frac{8 \beta^{2} L^{2}}{\mu^{2}}\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2}\right) \mathbb{E}\left\|y_{k-1}^{T}-y^{*}\left(x_{k-1}\right)\right\|^{2}+\frac{4 \beta^{2} L^{2}}{\mu^{2}} \mathbb{E}\left\|\nabla \Phi\left(x_{k-1}\right)\right\|^{2} \\
&+\frac{4 \beta^{2} L^{2}}{\mu^{2}}\left(\frac{6 L^{2} M^{2}}{\mu^{2} D_{g}}+\left(\frac{6 L^{2}}{\mu^{2}}+2\right) \frac{M^{2}}{D_{f}}+\frac{12 \eta^{2} L^{4} M^{2}}{\mu^{2}} \frac{1}{B}+\frac{12 L^{2} M^{2}(1-\eta \mu)^{2 Q+2}}{\mu^{2}}\right) \tag{44}
\end{align*}
$$

Combining eq. 42 and eq. 44 yields

$$
\begin{align*}
& \mathbb{E}\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|^{2} \\
& \leq\left(\frac{L-\mu}{L+\mu}\right)^{2 T}\left(2+\frac{8 \beta^{2} L^{2}}{\mu^{2}}\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2}\right) \mathbb{E}\left\|y_{k-1}^{T}-y^{*}\left(x_{k-1}\right)\right\|^{2} \\
&+\left(\frac{L-\mu}{L+\mu}\right)^{2 T} \frac{4 \beta^{2} L^{2}}{\mu^{2}}\left(\frac{6 L^{2} M^{2}}{\mu^{2} D_{g}}+\left(\frac{6 L^{2}}{\mu^{2}}+2\right) \frac{M^{2}}{D_{f}}+\frac{12 \eta^{2} L^{4} M^{2}}{\mu^{2}} \frac{1}{B}+\frac{12 L^{2} M^{2}(1-\eta \mu)^{2 Q+2}}{\mu^{2}}\right) \\
&+\frac{4 \beta^{2} L^{2}}{\mu^{2}}\left(\frac{L-\mu}{L+\mu}\right)^{2 T} \mathbb{E}\left\|\nabla \Phi\left(x_{k-1}\right)\right\|^{2}+\frac{\sigma^{2}}{L \mu S} \tag{45}
\end{align*}
$$

Based on the definitions of $\lambda, \omega, \Delta$ in eq. 38, we obtain from eq. 45 that

$$
\begin{equation*}
\mathbb{E}\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|^{2} \leq \lambda \mathbb{E}\left\|y_{k-1}^{T}-y^{*}\left(x_{k-1}\right)\right\|^{2}+\omega \Delta+\frac{\sigma^{2}}{L \mu S}+\omega \mathbb{E}\left\|\nabla \Phi\left(x_{k-1}\right)\right\|^{2} \tag{46}
\end{equation*}
$$

Telescoping eq. 46) over $k$ yields

$$
\begin{aligned}
& \mathbb{E}\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|^{2} \\
& \quad \leq \lambda^{k} \mathbb{E}\left\|y_{0}^{T}-y^{*}\left(x_{0}\right)\right\|^{2}+\omega \sum_{j=0}^{k-1} \lambda^{k-1-j} \mathbb{E}\left\|\nabla \Phi\left(x_{j}\right)\right\|^{2}+\frac{\omega \Delta+\frac{\sigma^{2}}{L \mu S}}{1-\lambda} \\
& \quad \leq \lambda^{k}\left(\left(\frac{L-\mu}{L+\mu}\right)^{2 T}\left\|y_{0}-y^{*}\left(x_{0}\right)\right\|^{2}+\frac{\sigma^{2}}{L \mu S}\right)+\omega \sum_{j=0}^{k-1} \lambda^{k-1-j} \mathbb{E}\left\|\nabla \Phi\left(x_{j}\right)\right\|^{2}+\frac{\omega \Delta+\frac{\sigma^{2}}{L \mu S}}{1-\lambda}
\end{aligned}
$$

which completes the proof.

## F. 3 Proof of Theorem 2

In this subsection, we provide the proof for Theorem 2, based on the supporting lemmas we develop in Appendix F. 2

Based on the smoothness of the function $\Phi(x)$ in Lemma 2, we have

$$
\begin{aligned}
\Phi\left(x_{k+1}\right) & \leq \Phi\left(x_{k}\right)+\left\langle\nabla \Phi\left(x_{k}\right), x_{k+1}-x_{k}\right\rangle+\frac{L_{\Phi}}{2}\left\|x_{k+1}-x_{k}\right\|^{2} \\
& \leq \Phi\left(x_{k}\right)-\beta\left\langle\nabla \Phi\left(x_{k}\right), \widehat{\nabla} \Phi\left(x_{k}\right)\right\rangle+\beta^{2} L_{\Phi}\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2}+\beta^{2} L_{\Phi}\left\|\nabla \Phi\left(x_{k}\right)-\widehat{\nabla} \Phi\left(x_{k}\right)\right\|^{2}
\end{aligned}
$$

For simplicity, let $\mathbb{E}_{k}=\mathbb{E}\left(\cdot \mid x_{k}, y_{k}^{T}\right)$. Note that we choose $\beta=\frac{1}{4 L_{\phi}}$. Then, taking expectation over the above inequality, we have

$$
\begin{align*}
& \mathbb{E} \Phi\left(x_{k+1}\right) \leq \leq \mathbb{E} \Phi\left(x_{k}\right)-\beta \mathbb{E}\left\langle\nabla \Phi\left(x_{k}\right), \mathbb{E}_{k} \widehat{\nabla} \Phi\left(x_{k}\right)\right\rangle+\beta^{2} L_{\Phi} \mathbb{E}\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2} \\
&+\beta^{2} L_{\Phi} \mathbb{E}\left\|\nabla \Phi\left(x_{k}\right)-\widehat{\nabla} \Phi\left(x_{k}\right)\right\|^{2} \\
& \stackrel{(i)}{\leq} \\
& \mathbb{E} \Phi\left(x_{k}\right)+\frac{\beta}{2} \mathbb{E}\left\|\mathbb{E}_{k} \widehat{\nabla} \Phi\left(x_{k}\right)-\nabla \Phi\left(x_{k}\right)\right\|^{2}-\frac{\beta}{4} \mathbb{E}\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2}+\frac{\beta}{4} \mathbb{E}\left\|\nabla \Phi\left(x_{k}\right)-\widehat{\nabla} \Phi\left(x_{k}\right)\right\|^{2} \\
& \quad(i i) \\
& \leq \mathbb{E} \Phi\left(x_{k}\right)-\frac{\beta}{4} \mathbb{E}\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2}+\frac{\beta L^{2} M^{2}(1-\eta \mu)^{2 Q}}{\mu^{2}}  \tag{47}\\
&+\frac{\beta}{4}\left(\frac{6 L^{2} M^{2}}{\mu^{2} D_{g}}+\left(\frac{6 L^{2}}{\mu^{2}}+2\right) \frac{M^{2}}{D_{f}}+\frac{12 \eta^{2} L^{4} M^{2}}{\mu^{2}} \frac{1}{B}+\frac{12 L^{2} M^{2}(1-\eta \mu)^{2 Q+2}}{\mu^{2}}\right) \\
&+\frac{5 \beta}{4}\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2} \mathbb{E}\left\|y_{k}^{T}-y^{*}\left(x_{k}\right)\right\|^{2}
\end{align*}
$$

where ( $i$ ) follows from Cauchy-Schwarz inequality, and (ii) follows from Lemma 3 and Lemma 4 . To simplify notations, Let

$$
\begin{equation*}
\nu=\frac{5}{4}\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2} \tag{48}
\end{equation*}
$$

Then, applying Lemma 5 in eq. (47) and using the definitions of $\omega, \Delta, \lambda$ in eq. (38), we have

$$
\begin{aligned}
\mathbb{E} \Phi\left(x_{k+1}\right) \leq & \mathbb{E} \Phi\left(x_{k}\right)-\frac{\beta}{4} \mathbb{E}\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2}+\frac{\beta L^{2} M^{2}(1-\eta \mu)^{2 Q}}{\mu^{2}} \\
& +\frac{\beta}{4} \Delta+\beta \nu \lambda^{k}\left(\left(\frac{L-\mu}{L+\mu}\right)^{2 T}\left\|y_{0}-y^{*}\left(x_{0}\right)\right\|^{2}+\frac{\sigma^{2}}{L \mu S}\right) \\
& +\beta \nu \omega \sum_{j=0}^{k-1} \lambda^{k-1-j} \mathbb{E}\left\|\nabla \Phi\left(x_{j}\right)\right\|^{2}+\frac{\beta \nu\left(\omega \Delta+\frac{\sigma^{2}}{L \mu S}\right)}{1-\lambda},
\end{aligned}
$$

Telescoping the above inequality over $k$ from 0 to $K-1$ yields

$$
\begin{aligned}
\mathbb{E} \Phi\left(x_{K}\right) \leq \Phi\left(x_{0}\right)- & \frac{\beta}{4} \sum_{k=0}^{K-1} \mathbb{E}\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2}+\beta \nu \omega \sum_{k=1}^{K-1} \sum_{j=0}^{k-1} \lambda^{k-1-j} \mathbb{E}\left\|\nabla \Phi\left(x_{j}\right)\right\|^{2} \\
& +\frac{K \beta \Delta}{4}+\left(\left(\frac{L-\mu}{L+\mu}\right)^{2 T}\left\|y_{0}-y^{*}\left(x_{0}\right)\right\|^{2}+\frac{\sigma^{2}}{L \mu S}\right) \frac{\beta \nu}{1-\lambda} \\
& +\frac{K \beta L^{2} M^{2}(1-\eta \mu)^{2 Q}}{\mu^{2}}+\frac{K \beta \nu\left(\omega \Delta+\frac{\sigma^{2}}{L \mu S}\right)}{1-\lambda}
\end{aligned}
$$

which, using the fact that

$$
\sum_{k=1}^{K-1} \sum_{j=0}^{k-1} \lambda^{k-1-j} \mathbb{E}\left\|\nabla \Phi\left(x_{j}\right)\right\|^{2} \leq\left(\sum_{k=0}^{K-1} \lambda^{k}\right) \sum_{k=0}^{K-1} \mathbb{E}\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2}<\frac{1}{1-\lambda} \sum_{k=0}^{K-1} \mathbb{E}\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2}
$$

yields

$$
\begin{align*}
\left(\frac{1}{4}-\right. & \left.\frac{\nu \omega}{1-\lambda}\right) \frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E}\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2} \\
\leq & \frac{\Phi\left(x_{0}\right)-\inf _{x} \Phi(x)}{\beta K}+\frac{\nu\left(\left(\frac{L-\mu}{L+\mu}\right)^{2 T}\left\|y_{0}-y^{*}\left(x_{0}\right)\right\|^{2}+\frac{\sigma^{2}}{L \mu S}\right)}{K(1-\lambda)}+\frac{\Delta}{4}+\frac{L^{2} M^{2}(1-\eta \mu)^{2 Q}}{\mu^{2}} \\
& \quad+\frac{\nu\left(\omega \Delta+\frac{\sigma^{2}}{L \mu S}\right)}{1-\lambda} \tag{49}
\end{align*}
$$

Since $\beta=\frac{1}{4 L_{\Phi}}$ and $T \geq \frac{\log \left(12+\frac{48 \beta^{2} L^{2}}{\mu^{2}}\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2}\right)}{2 \log \left(\frac{L+\mu}{L-\mu}\right)}$, we have $\lambda \leq \frac{1}{6}$, and hence eq. 49 is further simplified to

$$
\begin{align*}
\left(\frac{1}{4}-\right. & \left.\frac{6}{5} \nu \omega\right) \frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E}\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2} \\
\leq & \frac{\Phi\left(x_{0}\right)-\inf _{x} \Phi(x)}{\beta K}+\frac{2 \nu\left(\left(\frac{L-\mu}{L+\mu}\right)^{2 T}\left\|y_{0}-y^{*}\left(x_{0}\right)\right\|^{2}+\frac{\sigma^{2}}{L \mu S}\right)}{K}+\frac{\Delta}{4}+\frac{L^{2} M^{2}(1-\eta \mu)^{2 Q}}{\mu^{2}} \\
& +2 \nu\left(\omega \Delta+\frac{\sigma^{2}}{L \mu S}\right) \tag{50}
\end{align*}
$$

By the definitions of $\omega$ in eq. 38 and $\nu$ in eq. 48 and $T \geq \frac{\log \left(12+\frac{48 \beta^{2} L^{2}}{\mu^{2}}\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2}\right)}{2 \log \left(\frac{L+\mu}{L-\mu}\right)}$, we have

$$
\begin{align*}
\nu \omega=\frac{5 \beta^{2} L^{2}}{\mu^{2}} & \left(\frac{L-\mu}{L+\mu}\right)^{2 T}\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2} \\
& <\frac{\frac{5 \beta^{2} L^{2}}{\mu^{2}}\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2}}{12+\frac{48 \beta^{2} L^{2}}{\mu^{2}}\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2}} \leq \frac{5}{48} . \tag{51}
\end{align*}
$$

In addition, since $T>\frac{\log \left(\sqrt{\beta}\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)\right)}{\log \left(\frac{L+\mu}{L-\mu}\right)}$, we have

$$
\begin{equation*}
\nu\left(\frac{L-\mu}{L+\mu}\right)^{2 T}=\frac{5}{4}\left(\frac{L-\mu}{L+\mu}\right)^{2 T}\left(L+\frac{L^{2}}{\mu}+\frac{M \tau}{\mu}+\frac{L M \rho}{\mu^{2}}\right)^{2}<\frac{5}{4 \beta} . \tag{52}
\end{equation*}
$$

Substituting eq. (51) and eq. (52) in eq. (50) yields

$$
\begin{align*}
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E}\left\|\nabla \Phi\left(x_{k}\right)\right\|^{2} \leq & \frac{8\left(\Phi\left(x_{0}\right)-\inf _{x} \Phi(x)+\frac{5}{2}\left\|y_{0}-y^{*}\left(x_{0}\right)\right\|^{2}\right)}{\beta K}+\left(1+\frac{1}{K}\right) \frac{16 \nu \sigma^{2}}{L \mu S} \\
& +\frac{11}{3} \Delta+\frac{8 L^{2} M^{2}}{\mu^{2}}(1-\eta \mu)^{2 Q} \tag{53}
\end{align*}
$$

which, in conjunction with eq. (38) and eq. 48, yields eq. (8) in Theorem 2.

Then, based on eq. (8), in order to achieve an $\epsilon$-accurate stationary point, i.e., $\mathbb{E}\|\nabla \Phi(\bar{x})\|^{2} \leq \epsilon$ with $\bar{x}$ chosen from $x_{0}, \ldots, x_{K-1}$ uniformly at random, it suffices to choose

$$
\begin{aligned}
& K=\frac{32 L_{\Phi}\left(\Phi\left(x_{0}\right)-\inf _{x} \Phi(x)+\frac{5}{2}\left\|y_{0}-y^{*}\left(x_{0}\right)\right\|^{2}\right)}{\epsilon}=\mathcal{O}\left(\frac{\kappa^{3}}{\epsilon}\right), T=\Theta(\kappa) \\
& Q=\kappa \log \frac{\kappa^{2}}{\epsilon}, S=\mathcal{O}\left(\frac{\kappa^{5}}{\epsilon}\right), D_{g}=\mathcal{O}\left(\frac{\kappa^{2}}{\epsilon}\right), D_{f}=\mathcal{O}\left(\frac{\kappa^{2}}{\epsilon}\right), B=\mathcal{O}\left(\frac{\kappa^{2}}{\epsilon}\right)
\end{aligned}
$$

Note that the above choices of $Q$ and $B$ satisfy the condition that $B \geq \frac{1}{Q(1-\eta \mu)^{Q-1}}$ required in Proposition 4 .
Then, the gradient complexity is given by $\operatorname{Gc}(F, \epsilon)=K D_{f}=\mathcal{O}\left(\kappa^{5} \epsilon^{-2}\right), \operatorname{Gc}(G, \epsilon)=K T S=\mathcal{O}\left(\kappa^{9} \epsilon^{-2}\right)$. In addition, the high-order derivative complexity is given by $\operatorname{Hxy}(G, \epsilon)=K D_{g}=\mathcal{O}\left(\kappa^{5} \epsilon^{-2}\right)$, and the Hessian computational complexity is given by

$$
\operatorname{Hyy}(G, \epsilon)=K \sum_{j=1}^{Q} B Q(1-\eta \mu)^{j-1}=\frac{K B Q}{\eta \mu} \leq \mathcal{O}\left(\frac{\kappa^{6}}{\epsilon^{2}} \log \frac{\kappa^{2}}{\epsilon}\right)
$$

Then, the proof is complete.

## G Proof of Theorem 3 on meta-learning

To prove Theorem 3, we first establish the following lemma to characterize the estimation variance $\mathbb{E}_{\mathcal{B}}\left\|\frac{\partial \mathcal{L}_{\mathcal{D}}\left(\phi_{k}, \widetilde{w}_{k}^{T} ; \mathcal{B}\right)}{\partial \phi_{k}}-\frac{\overrightarrow{\partial \mathcal{L}}_{\mathcal{D}}\left(\phi_{k}, \widetilde{w}_{k}^{T}\right)}{\partial \phi_{k}}\right\|^{2}$, where $\widetilde{w}_{k}^{T}$ is the output of $T$ inner-loop steps of gradient descent at the $k^{t h}$ outer loop.

Lemma 6. Suppose Assumptions 2 and 3 are satisfied and suppose each task loss $\mathcal{L}_{\mathcal{S}_{i}}\left(\phi, w_{i}\right)$ is $\mu$-stronglyconvex w.r.t. $w_{i}$. Then, we have

$$
\mathbb{E}_{\mathcal{B}}\left\|\frac{\partial \mathcal{L}_{\mathcal{D}}\left(\phi_{k}, \widetilde{w}_{k}^{T} ; \mathcal{B}\right)}{\partial \phi_{k}}-\frac{\partial \mathcal{L}_{\mathcal{D}}\left(\phi_{k}, \widetilde{w}_{k}^{T}\right)}{\partial \phi_{k}}\right\|^{2} \leq\left(1+\frac{L}{\mu}\right)^{2} \frac{M^{2}}{|\mathcal{B}|}
$$

Proof. Let $\widetilde{w}_{k}^{T}=\left(w_{1, k}^{T}, \ldots, w_{m, k}^{T}\right)$ be the output of $T$ inner-loop steps of gradient descent at the $k^{\text {th }}$ outer loop. Using Proposition 1, we have, for task $\mathcal{T}_{i}$,

$$
\begin{align*}
\left\|\frac{\partial \mathcal{L}_{\mathcal{D}_{i}}\left(\phi_{k}, w_{i, k}^{T}\right)}{\partial \phi_{k}}\right\| & \left\|\leq \nabla_{\phi} \mathcal{L}_{\mathcal{D}_{i}}\left(\phi_{k}, w_{i, k}^{T}\right)\right\| \\
+ & \left\|\alpha \sum_{t=0}^{T-1} \nabla_{\phi} \nabla_{w_{i}} \mathcal{L}_{\mathcal{S}_{i}}\left(\phi_{k}, w_{i, k}^{t}\right) \prod_{j=t+1}^{T-1}\left(I-\alpha \nabla_{w_{i}}^{2} \mathcal{L}_{\mathcal{S}_{i}}\left(\phi_{k}, w_{i, k}^{j}\right)\right) \nabla_{w_{i}} \mathcal{L}_{\mathcal{D}_{i}}\left(\phi_{k}, w_{i . k}^{T}\right)\right\| \\
& \quad{ }^{(i)} \leq M+\alpha L M \sum_{t=0}^{T-1}(1-\alpha \mu)^{T-t-1}=M+\frac{L M}{\mu} \tag{54}
\end{align*}
$$

where (i) follows from assumptions 2 and strong-convexity of $\mathcal{L}_{\mathcal{S}_{i}}(\phi, \cdot)$. Then, using the definition of $\mathcal{L}_{\mathcal{D}}(\phi, \widetilde{w} ; \mathcal{B})=\frac{1}{|\mathcal{B}|} \sum_{i \in \mathcal{B}} \mathcal{L}_{\mathcal{D}_{i}}\left(\phi, w_{i}\right)$, we have

$$
\begin{align*}
\mathbb{E}_{\mathcal{B}}\left\|\frac{\partial \mathcal{L}_{\mathcal{D}}\left(\phi_{k}, \widetilde{w}_{k}^{T} ; \mathcal{B}\right)}{\partial \phi_{k}}-\frac{\partial \mathcal{L}_{\mathcal{D}}\left(\phi_{k}, \widetilde{w}_{k}^{T}\right)}{\partial \phi_{k}}\right\|^{2} & =\frac{1}{|\mathcal{B}|} \mathbb{E}_{i}\left\|\frac{\partial \mathcal{L}_{\mathcal{D}_{i}}\left(\phi_{k}, w_{i, k}^{T}\right)}{\partial \phi_{k}}-\frac{\partial \mathcal{L}_{\mathcal{D}}\left(\phi_{k}, \widetilde{w}_{k}^{T}\right)}{\partial \phi_{k}}\right\|^{2} \\
& \stackrel{(i)}{\leq} \frac{1}{|\mathcal{B}|} \mathbb{E}_{i}\left\|\frac{\partial \mathcal{L}_{\mathcal{D}_{i}}\left(\phi_{k}, w_{i, k}^{T}\right)}{\partial \phi_{k}}\right\|^{2} \\
& \stackrel{(i i)}{\leq}\left(1+\frac{L}{\mu}\right)^{2} \frac{M^{2}}{|\mathcal{B}|} \tag{55}
\end{align*}
$$

where ( $i$ ) follows from $\mathbb{E}_{i} \frac{\partial \mathcal{L}_{\mathcal{D}_{i}}\left(\phi_{k}, w_{i, k}^{T}\right)}{\partial \phi_{k}}=\frac{\partial \mathcal{L}_{\mathcal{D}}\left(\phi_{k}, \widetilde{w}_{k}^{T}\right)}{\partial \phi_{k}}$ and (ii) follows from eq. 54 . Then, the proof is complete.

Proof of Theorem 3. Recall $\Phi(\phi):=\mathcal{L}_{\mathcal{D}}\left(\phi, \widetilde{w}^{*}(\phi)\right)$ be the objective function, and let $\widehat{\nabla} \Phi\left(\phi_{k}\right)=\frac{\partial \mathcal{L}_{\mathcal{D}}\left(\phi_{k}, \widetilde{w}_{k}^{T}\right)}{\partial \phi_{k}}$. Using an approach similar to eq. (24), we have

$$
\begin{align*}
\Phi\left(\phi_{k+1}\right) & \leq \Phi\left(\phi_{k}\right)+\left\langle\nabla \Phi\left(\phi_{k}\right), \phi_{k+1}-\phi_{k}\right\rangle+\frac{L_{\Phi}}{2}\left\|\phi_{k+1}-\phi_{k}\right\|^{2} \\
& \leq \Phi\left(\phi_{k}\right)-\beta\left\langle\nabla \Phi\left(\phi_{k}\right), \frac{\partial \mathcal{L}_{\mathcal{D}}\left(\phi_{k}, \widetilde{w}_{k}^{T} ; \mathcal{B}\right)}{\partial \phi_{k}}\right\rangle+\frac{\beta^{2} L_{\Phi}}{2}\left\|\frac{\partial \mathcal{L}_{\mathcal{D}}\left(\phi_{k}, \widetilde{w}_{k}^{T} ; \mathcal{B}\right)}{\partial \phi_{k}}\right\|^{2} . \tag{56}
\end{align*}
$$

Taking the expectation of eq. 56) yields

$$
\begin{align*}
\mathbb{E} \Phi\left(\phi_{k+1}\right) \stackrel{(i)}{\leq} & \mathbb{E} \Phi\left(\phi_{k}\right)-\beta \mathbb{E}\left\langle\nabla \Phi\left(\phi_{k}\right), \widehat{\nabla} \Phi\left(\phi_{k}\right)\right\rangle+\frac{\beta^{2} L_{\Phi}}{2} \mathbb{E}\left\|\widehat{\nabla} \Phi\left(\phi_{k}\right)\right\|^{2} \\
& +\frac{\beta^{2} L_{\Phi}}{2} \mathbb{E}\left\|\widehat{\nabla} \Phi\left(\phi_{k}\right)-\frac{\partial \mathcal{L}_{\mathcal{D}}\left(\phi_{k}, \widetilde{w}_{k}^{T} ; \mathcal{B}\right)}{\partial \phi_{k}}\right\|^{2} \\
\quad{ }^{(i i)} \leq & \mathbb{E} \Phi\left(\phi_{k}\right)-\beta \mathbb{E}\left\langle\nabla \Phi\left(\phi_{k}\right), \widehat{\nabla} \Phi\left(\phi_{k}\right)\right\rangle+\frac{\beta^{2} L_{\Phi}}{2} \mathbb{E}\left\|\widehat{\nabla} \Phi\left(\phi_{k}\right)\right\|^{2}+\frac{\beta^{2} L_{\Phi}}{2}\left(1+\frac{L}{\mu}\right)^{2} \frac{M^{2}}{|\mathcal{B}|} \\
\leq & \mathbb{E} \Phi\left(\phi_{k}\right)-\left(\frac{\beta}{2}-\beta^{2} L_{\Phi}\right) \mathbb{E}\left\|\nabla \Phi\left(\phi_{k}\right)\right\|^{2}+\left(\frac{\beta}{2}+\beta^{2} L_{\Phi}\right) \mathbb{E}\left\|\nabla \Phi\left(\phi_{k}\right)-\widehat{\nabla} \Phi\left(\phi_{k}\right)\right\|^{2} \\
& +\frac{\beta^{2} L_{\Phi}}{2}\left(1+\frac{L}{\mu}\right)^{2} \frac{M^{2}}{|\mathcal{B}|}, \tag{57}
\end{align*}
$$

where $(i)$ follows from $\mathbb{E}_{\mathcal{B}} \mathcal{L}_{\mathcal{D}}\left(\phi_{k}, \widetilde{w}_{k}^{T} ; \mathcal{B}\right)=\mathcal{L}_{\mathcal{D}}\left(\phi_{k}, \widetilde{w}_{k}^{T}\right)$ and (ii) follows from Lemma 6 Using Proposition 3 in eq. (57) and rearranging the terms, we have

$$
\begin{aligned}
& \frac{1}{K} \sum_{k=0}^{K-1}\left(\frac{1}{2}-\beta L_{\Phi}\right) \mathbb{E}\left\|\nabla \Phi\left(\phi_{k}\right)\right\|^{2} \\
& \quad \leq \frac{\Phi\left(\phi_{0}\right)-\inf _{\phi} \Phi(\phi)}{\beta K}+3\left(\frac{1}{2}+\beta L_{\Phi}\right) \frac{L^{2} M^{2}(1-\alpha \mu)^{2 T}}{\mu^{2}}+\frac{\beta L_{\Phi}}{2}\left(1+\frac{L}{\mu}\right)^{2} \frac{M^{2}}{|\mathcal{B}|} \\
& \quad+3 \Delta\left(\frac{1}{2}+\beta L_{\Phi}\right)\left(\frac{L^{2}(L+\mu)^{2}}{\mu^{2}}(1-\alpha \mu)^{T}+\frac{4 M^{2}(\tau \mu+L \rho)^{2}}{\mu^{4}}(1-\alpha \mu)^{T-1}\right)
\end{aligned}
$$

where $\Delta=\max _{k}\left\|\widetilde{w}_{k}^{0}-\widetilde{w}^{*}\left(\phi_{k}\right)\right\|^{2}<\infty$. Choose the same parameters $\beta, T$ as in Theorem 1 . Then, we have

$$
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E}\left\|\nabla \Phi\left(\phi_{k}\right)\right\|^{2} \leq \frac{16 L_{\Phi}\left(\Phi\left(\phi_{0}\right)-\inf _{\phi} \Phi(\phi)\right)}{K}+\frac{2 \epsilon}{3}+\left(1+\frac{L}{\mu}\right)^{2} \frac{M^{2}}{8|\mathcal{B}|}
$$

Then, the proof is complete.

[^0]:    ${ }^{1}$ We use a conjugate-gradient (CG) based approach to estimate the Hessian inverse in BA.
    ${ }^{2}$ ANIL refers to almost no inner loop, which is an efficient MAML variant with task-specific adaption on the last-layer parameters.
